It is admitted in Mr. Ladd's report that certain objections to the Ford offer seem apparent, but it is felt that none of the objections to the Ford offer can be remedied or solved by government ownership and operation at Muscle Shoals—by the government going into the power business or entering the hazardous field of operating nitrate plants at Muscle Shoals in the production of nitrogenous and other commercial fertilizers using electrochemical processes the commercial success of which is yet controversial. "For Congress to adopt such a policy, when Henry Ford's offer makes it unnecessary for the government to do so, would subject Congress to the just condemnation and reproach of all sober-minded people," says the report.

Senator Ladd's report then gives parallel quotations from the bill providing for lease and sale to Henry Ford and from the bill providing for government ownership and operation, and summarizes the Ford offer under twelve headings. The report then states what are considered as the four main advantages which will follow the acceptance of this offer:

Contribution to Defense

First, it will contribute to our national defense by providing a supply of the indispensable nitrates that must be had for the manufacture of explosives in time of war. The primary object in undertaking the Muscle Shoals project was to provide a supply of fixed nitrogen for explosives. Mr. Ford's offer agrees to maintain Nitrate Plant No. 2 for 100 years ready for immediate use, to carry on a program of research to determine the most improved methods of operation of such a plant, and to operate this plant continuously for the period of the lease.

Reduction in Fertilizer Price

Second, the Muscle Shoals project, under the Ford offer, provides a large-scale production of fertilizer under the most favorable conditions, which cannot fail to reduce the cost of fertilizer to the farmer. Confidence in this reduction of cost is held because of the statements of F. S. Washburn, who introduced the cyanamide process in this country, and because of the statements of the byproduct coke-oven interests in requesting protection for their ammonium-sulphate product, when they stated that fertilizer produced by the cyanamide process in Germany could be sold in this country at one-half the price of their product.

In any case the evidence is convincing to the minority of the Committee on Agriculture and Forestry that modern processes can be applied at Muscle Shoals in such a way as to reduce this cost and they feel that Mr. Ford has the cash to develop and adopt these processes. It is felt that the farmer can look for but little reduction of prices from the present fertilizer interests, who, protected by the Chilean export duty, are now asking for an import duty of $12 per ton in addition.

Development of Water Power

Third, the project developed under the Ford offer will contribute to the advancement of industry by introducing a plan of water-power development which provides the means whereby hydro-electric power ultimately may be had in the United States as cheaply as in the more naturally favored countries such as Canada and Norway.

Since a hydro-electric plant costs a great deal to construct and but little to operate, there is a feature of hydro-electric power economics well known to those in the business, that the general public probably does not appreciate. When the items which go to make up the cost of hydro-electric power at the switchboard of the generating station are examined, it is found that under the conditions of construction and financing existing in the United States, the single item of interest on the investment constitutes 80 per cent or more of the cost of the power.

Mr. Ford proposes to eliminate the interest by amortizing and returning the investment, through the operation of a long-time sinking fund. He therefore provides a series of payments which, when invested in a sinking fund at as low a rate of interest as 4½ per cent, will return the entire cost of both dams, including the $17,000,000 already expended by the government. This eliminates the capital charges and interest and ultimately reduces the cost of power to the mere cost of operation and maintenance, which in a large plant is from $1 to $3 per horsepower per year, or less than one-half of 1 mill per kilowatt-hour. Under this plan the bonded indebtedness on a water-power development is reduced instead of being increased as is the customary procedure in refinancing operations.

Navigation

Fourth, the project developed under the Ford offer will contribute to the early completion of permanent navigation improvement on one of the most important of our inland streams. It will provide an outlet by water for a section of the country having a great variety of useful raw materials and will do so under a plan which may be applied on other American power streams whereby the water power furnishes the government with its navigation facilities without cost.

This contribution to navigation is

(*Continued on page* 278)

Wood Pulp Goes on Free List

By a vote of 22 to 30 the Senate rejected the Finance Committee recommendation for a duty of 5 per cent ad valorem on chemical wood pulp. The tariff was urged by Chairman McCumber of the Senate Finance Committee, who said the industry is important and can produce for an indefinite period if given a protective tariff.

hemical Manufacturers Demand Reinstatement of Dye Embargo

A. O'Reilly Tells Synthetic Organic Chemical Manufacturers That Facts Must Be Presented to Legislators if Industry Is to Receive Consideration

ECLARING that the American chemical industry will be unable urvive the ruthless competition of great German cartel unless the em-go on foreign dyes is continued, fifty nbers of the Synthetic Organic mical Manufacturers Association of United States unanimously peti-ed the Senate Finance Committee reinstate the protective provisions ch had been eliminated after the e fight in the Senate on July 15.

his action followed an all-day ses- at the Hotel Pennsylvania, New k City, where Dr. Charles H. Herty, sident of the association, and rge A. O'Reilly, vice-president of Irving National Bank, led in the ussion of this serious problem of domestic organic chemical industry. unfavorable action of the Senate attributed by Dr. Herty to the con-on resulting from the controversy veen the government and the Chem- Foundation. In the course of his ussion he declared:

It is my belief that the recent vote he Senate, sitting as a committee of whole, was due to a confusion of ught in the minds of several Sena- between two issues—patents and tection for this industry. This con-on arises, I believe, from the recent on of the government in connection n the Chemical Foundation. Logi-y this has no connection with the sideration of the question of ade-te protection for this vitally im-tant American industry.

I sincerely hope that the confusion thought which existed at the time vote was taken in the Senate strik-out the provisions placed in the bill the Senate Finance Committee will cleared away and that these para-phs will be reinserted in the meas- before it is passed.

Unless this is done, I foresee the n of the American industry by the at German chemical cartel, with its years of experience and its vast re-rces, which has been so strenuously ting us through its agents in this ntry."

Banker Presents Views

The trouble with your industry is damental, not incidental," said A. O'Reilly, addressing the associa- at the luncheon which was held veen the morning and afternoon ions.

n a spirited address Mr. O'Reilly ared that the chemical industry will er receive the consideration it de-es, either by the public or by Con-s, until the futility of telegrams to ators, delegations to officials and lutions by societies is realized and industries send to Washington the men they have to "put over" their story. And these men must not be the theorists, or the talkers, or the wind merchants, but they must be the pick of the industry, the men who know more about their business than anyone else in the country—its history, its theory, its problems and its business phases. When the chemical industry adopts such a policy there will be less talk of the "blockheads in Washington" and less need for resolutions of protest.

Mr. O'Reilly is probably as familiar with the present-day problems of the chemical industry as anyone in the country not directly connected with it, and at the same time his viewpoint is impartial and unprejudiced.

Bankers are conservative by nature and by necessity. When approached with a new venture, their attitude is inevitably skeptical and before they will agree to back the new undertaking they must be convinced that it is sound, and convinced by irrefutable facts. In the absence of such conviction American bankers are still skeptical of the American chemical industry. Chemistry is out of their line. They know nothing about it. Consequently, the chemical venture can scarce hope to enlist their support.

"We bankers are coming out of our shells. We have begun to learn that we have to put our business forward as everyone else does who has anything to sell. You should break into the banking situation. Break into the banking consciousness. They would be glad to get into this with you. But we do not know. We are uninformed and misinformed."

Advertising Needed

The same situation exists with regard to the legislators. With one or two possible exceptions, our Congressmen are not "sold" on the American chemical industry any more than are the bankers or the public as a whole. In the face of adverse legislation the chemical industry has reached the point where it throws up its hands in disgust and exclaims, "What's the use, with such blockheads in Washington?"

Such an attitude is not only unjust but it betrays ignorance, said Mr. O'Reilly. The fact of the matter is that the great majority of our lawmakers are doing the best they can with something they don't know anything about. And the blame for this ignorance can fairly be laid at the door of the industry. The most earnest plea and the most patient explanation of one or two legislators who know enough about the chemical industry to lend it full support will be regarded merely as the propoganda of "special interests" until their colleagues—and, more important still, their constituents—are brought to realize the fundamental place that the chemical industry holds in their everyday lives.

Efforts Are Misdirected

The solution demands the adoption of a new policy by the industry, said the speaker. It demands a revised opinion of the mental capacity of our Congressmen. It demands the education of the individual and of the public to the true importance of the chemical industry and an education based not on resolutions, or petitions, or protests, but on facts. The representatives in Washington of the industry must be men with a broad knowledge and thorough understanding of the details and figures of the business they represent. Our Congressmen are swamped with telegrams and with the resolutions of a thousand and one organizations. They are forced into a skeptical attitude by a multitude of demands that are entirely one-sided and selfish. The one solution for the chemical industry is a concerted effort to advertise itself—to "sell" the idea of chemistry to the people of America.

The failure of the dye embargo, the antagonism to the C.W.S. and the Chemical Foundation situation are due to the same reticence.

Oil Discoveries Reported in Northern Alberta, Canada

Reports from the neighborhood of Fabyan, near Wainwright, where the Imperial Oil Co. is boring for oil, assert that the company has struck a heavy flow of oil, which flowed outside the precincts of the company's barbed-wire entanglement and converted the dust of the district into an oily mud. The company, however, refuses to confirm the report. The result of the rumor has been another run on the Dominion land office at Edmonton and filing of a large area of ground in the vicinity of the reported strike.

A number of companies are boring for oil at and near Pouce Coupe, which is situated close to the interprovincial boundary between Alberta and British Columbia. It will be remembered that the Imperial Oil Co. struck a heavy flow of gas in a well at Pouce Coupe last year. The gas has been shut out, and the well is now down 2,160 ft. The drill has passed through several strata of oily sand, and, it is said, will be continued to 4,200 ft., unless a commercial flow of oil is struck sooner.

The Pouce Coupe Oil Co. has a diamond drill in operation 10 miles to the south of the Imperial company's well, and is down 500 ft. and sinking at the rate of 60 ft. daily. The drill has a capacity of 3,000 ft.

The Great Slave Oil Co. is operating a similar outfit near Rolla, and is down 400 ft.

Northern Alberta Oil Fields, Ltd., has freighted in a large Californian drilling outfit, and is waiting instructions as to the particular point at which it is to be erected. The Mackenzie River Oil Co. has a similar drill in transit to Rolla.

National Safety Council Announces Its Annual Meeting

Detroit Scene of Elaborate Sessions, Including Many Discussions of Interest to Chemical Industries

THE eleventh annual meeting of members of the National Safety Council is announced for the week of Aug. 28 in Detroit, Mich. Sessions will be held in the Cass Technical High School and judging by the program as it stands to date, the proceedings will be of very lively interest, not only to safety workers but to many of the chemical industries. Among the speakers at the four days of meetings appear the names of many well-known engineers and executives of the chemical and allied fields.

The business of the Council will be disposed of at the opening session on Monday morning, Aug. 28. The general session the same afternoon will be under the chairmanship of George A. Walters, Deputy Commissioner of Police in Detroit, and a number of papers on the general status of safety work will be presented, among which is one by A. H. Lichty, vice-president of the Colorado Fuel & Iron Co. of Denver.

The general subject of plant publications and their function in spreading the safety habit will be discussed on Tuesday, under the chairmanship of A. Ellis Frampton, of the Hammermill Paper Co. of Erie, Pa.

General Session

The general session on Tuesday, Aug. 29, under the direction of H. W. Forster, vice-president of the Independence Bureau, Philadelphia, Pa., will include several papers of more than passing interest to chemical engineers. M. F. Crass, of the Grasselli Chemical Co., will read a paper on "Safety in the Handling and Use of Acids." F. A. Rogers, of Lewis Institute, Chicago, Ill., and H. H. Brown, of Norwood, Mass., will discuss static electricity, its occurrence and its hazards in industry, with special reference to safety devices for preventing or overcoming the danger. The discussion will be led by L. A. De Blois, of E. I. du Pont de Nemours & Co.

A general round table will be conducted by C. W. Price, of the Price-Rasmussen Corporation of Chicago, Wednesday afternoon. The program includes papers on several phases of accident prevention. J. M. Woltz, of the Youngstown Sheet & Tube Co., is chairman of the "ABC" session on Thursday morning and R. S. Quinby, of the Hood Rubber Co., will direct the discussion that afternoon on "Sanitation and Factory Housekeeping."

Section Meetings

Of special interest to the chemical industries will be the meetings of the chemical, cement, packers' and tanners', paper and pulp, petroleum and rubber sections. The chemical section is headed by S. H. Kershaw, of the Hercules Powder Co. Included in the program are papers by the following:

Walter G. Whitman, assistant professor of chemical engineering, Massachusetts Institute of Technology: "Safe Handling in Chemical Plants."

F. J. Hoxie, Associated Factory Mutual Fire Insurance Companies: "Preventing Vapor and Gas Explosions."

A. L. Watson, Hooker Electrochemical Co.: "Report by Industrial Poisons Committee."

Charles F. Horan, Hood Rubber Co.: "Benzol Poisoning, Its Occurrence and Prevention."

The cement section will discuss accident problems of the industry. The packers' and tanners' section has scheduled several papers relating to the welfare of workers in the packing and leather industries and to the efficient conduct of safety departments in those industries. The paper and pulp section is under the chairmanship of W. A. Gleason, of the Hammermill Paper Co., and the program includes papers on the special problems that confront the safety workers in the pulp and paper mill, particularly the hazards of unguarded machinery. In the petroleum industry, dangers are more likely to exist in the combustion of fuel oil or petroleum distillates, and several of the papers will touch on these hazards and their prevention. The rubber section will arouse considerable interest, as several papers are to be presented by delegates from the large rubber companies and a wide variety of subjects will be discussed. This section is under the chairmanship of H. T. Martin, of the Fisk Rubber Co. Besides the reports of several committees their sessions will include a talk entitled "Vulcanizers," by C. W. Cook.

Motion pictures, as usual, will contribute to the breadth of the sessions. A number of new films have been obtained and will be shown to demonstrate both new ideas in safety measures and the means that are being adopted to spread the council's propaganda.

An informal banquet will be held Thursday evening, for which several interesting features have been arranged.

American Institute of Chemical Engineers Plans Meeting

The American Institute of Chemical Engineers will hold a dinner in New York during the week of the Chemical Exposition, Sept. 11 to 16. Preliminary plans announce that the dinner will be held on Thursday. It will be preceded by a Council meeting. Ladies are to be invited to attend the dinner. Further announcement will be made when plans are completed. The arrangements are in charge of a committee of which David Wesson, of the Southern Cotton Oil Co., is chairman.

Federated Engineering Societi to Meet in Boston

Findings in a nationwide survey the three-shift day in American indu try will be placed before the executi board of the American Engineeri Council of the Federated American E gineering Societies, at a meeting of t board to be held in Boston on Sept. and 9.

Two reports, dealing with exhausti investigations of the two-shift and t three-shift day problems in numero industries will be presented. One, p pared by Horace B. Drury, formerly the faculty of Ohio State Universi will describe the extent of 2-shift ope tions in the continuous industries well as the procedure followed and t results noted by those companies whi have changed from the 2-shift day 12 hours each to the 3-shift day of hours each. Mr. Drury's report w discuss the general practicability abolishing 12-hour turns.

Among the industries investigat are the metals, glass, cement, li brick, pottery, chemicals, sugar, s petroleum, cottonseed and other ve table oils, paper, flour, rubber, g water and ice.

A second report on an investigat of the *modus operandi* involved changing the operations of a steel pl from 2-shift to 3-shift methods will made by Bradley Stoughton, forn secretary of the American Institute Mining and Metallurgical Enginee Both investigations are being direct by the American Engineering Counc committee on work periods in c tinuous operation industries.

Many national economic, political a social problems bound up with en neering will probably also be consider at the Boston meeting. The question government reorganization, involvi a proposal to establish a national d partment of public works, reforest tion problems, international affiliati with engineering societies, flood c trol and water supply, and plans the country-wide expansion of the F erated American Engineering Societ will be discussed, in addition to repo of numerous committees which are c sidering questions of national inter

Mortimer E. Cooley, dean of the E gineering Schools of the University Michigan, will preside.

Acts on Foundation Patents

The committee on procedure adopt and sent to President Harding a re lution expressing the hope that no tion will be taken by the federal g ernment regarding the recovery of tents from the Chemical Foundati until representatives of chemis chemical engineers, chemical manuf turers, the medical profession a others most directly concerned heard.

The resolution "implores t nothing be done which can, in any w or to the slightest extent, tend tow the ultimate return to former owne of patents or other property, lawfu sequestered and sold to Americans.

Japan Rejects Proposal for Dye Embargo

l Tariff of 35 Per Cent ad Valorem Must Meet Condition Analogous to That in U. S.

Japan has declined to grant either lye embargo or higher rates to pro- t it from foreign imports, according a cablegram from Commercial At- hé Abbott, at Tokyo, received at the partment of Commerce. The dye uation in Japan is analogous to that America, the industry having been eloped since the war and just becom- established. Recent cablegrams had licated that the licensing system uld be adopted, hence the final report me as a surprise. The domestic nufacturers were asking an increase duties of from 35 per cent ad valorem 70 per cent and a licensing system cover eighteen colors satisfactorily oduced in Japan.

The market for Japanese dyestuffs is w limited to buyers in nearby Orien- markets, and even then quotations l sales must be made at an extremely price. The local Japanese market quite overstocked with German goods, ainst which American, French and lian dyes are competing. On the er hand the depressed conditions of textile trade furnishes little relief the excessive stock of dyes.

t is indicated that the present rate 35 per cent ad valorem will stand hout any increase, and that no spe- l provisions will be adopted.

The total requirements of Japan ount to approximately $15,000,000 nually. Of this amount imports are out 50 per cent. Recent importations m Germany and Italy have amounted about $7,000,000 annually, with 0,000 from the United States.

The colors of Japanese manufacture ich are generally giving a degree of isfaction in the home market and which protection against imported ds is desired are: Rhodamine B, line methyl violet, bismarck brown, t red A, malachite green, direct ck, naphthol brown, cotton violet, phur black, sulphur brown, magenta, nge A, and Congo red.

Grasselli Gets Freight Refund on Iron Pyrites Shipments

The Grasselli Chemical Co. is to re- ve a refund of about $2,000 from the lroads which levied unreasonable ight rates on shipments of iron rites between DeKalb and Newcastle, The Interstate Commerce Commis- n, in an opinion just handed down, s ruled that the freight charges were reasonable to the extent that they ceeded $3.90 per long ton. The ship- nts were made when labor troubles vented the obtaining of supplies of c ore at the company's sulphuric d plant. Iron pyrites were substi- ed and 43 carloads were moved. A e of 5.30 was assessed on the ground t it was a sporadic movement. The mmission decided that in view of the fact that 3,163,660 lb. had moved the chemical company was entitled to a rate which would accord with the general ton-mile earnings within the territory concerned.

In the complaint of the Arlington Silver Mining Co. an examiner of the Interstate Commerce Commission has recommended that rates on ore from Okanogan to Tacoma, Wash., be held unreasonable.

Unreasonable rates on bauxite ore from various points to Omaha are alleged in a complaint to the Interstate Commerce Commission by the Metropolitan Utilities District of that city.

Experimental Therapy Institute Planned for Philadelphia

The creation of a national institute of experimental therapy, to have relatively the same scope as the Rockefeller Institute in pathology or the Mayo clinics in surgery, is the plan of Rear Admiral William C. Braisted, retired, for the expansion of the Philadelphia College of Pharmacy and Science, of which he is president.

The college soon is to leave its present site for newer and more commodious quarters in West Philadelphia. A plot has been acquired in this section of the city and work on the new college edifice will begin within the year.

Demand Dye Embargo

(*Continued from page* 275)

The speaker cited as an example of what could be done by the intelligent presentation of the facts the case of the manganese producers in the recent tariff wrangle. The position of the manganese producers threatened to be even less enviable than that of the dye manufacturers, but the businesslike efforts of capable representatives succeeded in convincing the legislators that the industry needed and deserved protection.

Manufacturers' Petition

The petition sent to members of the Senate Finance Committee read as follows:

> At a meeting of the Synthetic Organic Chemical Manufacturers Association of the United States, held at New York, Aug. 4, 1922, the undersigned manufacturers of dyes, drugs and other organic chemicals gave consideration to the serious danger that threatens their industry by reason of the defeat of the dye and chemical control act in the Senate, July 15. They now respectfully petition the Finance Committee to take such action as may be appropriate to reinstate the clauses in the tariff act stricken out by the Senate's action. They repeat what they have heretofore testified to before your committee, that nothing less than the provisions of the dye and chemical control act will adequately protect their industry; that no specific or ad valorem rates will prevent the German cartel from regaining absolute control of the American organic chemical market; and that the manufacture of dyes, medicinals and other organic chemicals can no longer be maintained in this country without the legislative protection heretofore advocated by your committee after thorough investigation of all the facts.

The business meetings were, as usual, conducted behind closed doors.

A.C.S. Secretary Reports on Conditions in Europe

After a visit to several European countries, during which he attended meetings of the International Union of Pure and Applied Chemistry and of the Société Chimie Industrielle, C. L. Parsons, secretary of the American Chemical Society, returns to this country with the report that the chemical industry in Germany is booming, but in the other European countries it is having great difficulty in emerging from the depression.

Germany is employing in the European countries the same questionable methods it is using in this country to regain its chemical supremacy, says Dr. Parsons, the only difference being that the German efforts are less effective abroad because the Europeans know them better. The consumers of dyes in European countries, Dr. Parsons asserts, seem to have more vision than those in this country and do not permit themselves to be made the agency through which Germany is trying to attain her ambitions. Then, too, officials in high places in England are not permitting themselves to be used to the permanent injury of their country's chemical industry, he says. There is no counterpart of Senator Moses in the English Parliament.

Nevertheless, Dr. Parsons reports, such headway as the Germans have made in the European countries has been by employing the same methods they have used here by obtaining a certain amount of co-operation with short-sighted consumers of their products and by having the whole-hearted support of importers.

Dr. Parsons was particularly impressed during his trip by the distinct advances which the English have made in the oxidation of ammonia; by the success and great possibilities of the new process for vulcanizing rubber by the action of sulphur dioxide and hydrogen sulphide; by the remarkable results made in the enameling of iron, and by the efficiency which the French have achieved in applying two colors in the same dyeing vat.

During the meetings which Dr. Parsons attended, several references were made to the advantages which American chemists possess by having only one national organization. The influence of chemists in several countries in Europe is impaired materially, it was stated, by multiplicity of organizations.

National Lead Charged With Price Fixing

A complaint of unfair competition has been made by the Federal Trade Commission against the National Lead Co. It charges the company with enforcing a system of fixing and maintaining specified standard prices at which its white lead, litharge and paint products are sold, through a system of support and co-operation of wholesale and retail dealers.

Minority Favors Ford

(Continued from page 274)

regarded as an important part of the Ford offer and an added reason for its acceptance.

Objection to Ford Offer

One of the principal objections to this offer lies in the 100-year lease. The Ladd report, in view of the fact that the rights of those with whom Mr. Ford would compete are either perpetual or not less than 99 years, feels that this time of lease is only fair.

It is also claimed that acceptance of the offer would give Mr. Ford a government subsidy in the development of power and the manufacture of fertilizer.

In rebuttal, the report cites a comparison between the Ladd bill and that proposing federal relief for the merchant marine, showing that the former called for an expenditure of $42,000,000, while the latter required an expenditure of $125,000,000, and asks how the subsidy to ship operators can be supported, while the Ford offer is condemned on the same grounds.

The Matter of Repairs

It has been maintained that the $55,000 payable by Mr. Ford annually for the maintenance and operation of the locks and dams, outside of the power houses, is insufficient but the Chief of Engineers has testified that this is a sufficient sum (House hearings, p. 19), and his testimony is confirmed by the experience of the Reclamation Service, for it is shown in the record that such large dams as the Arrow Rock (about half the size of Dam No. 2, 349 ft. high), built in 1915, has required an average for the maintenance expense of $950 since it was completed, the amount for the calendar year 1920 being only $567. This is not an isolated exception, as is evident from the record of seven large dams, the most expensive of which in 1920 was the Pathfinder Dam, 218 ft. high, built in 1909, which required $1,304 for its maintenance.

As in the case of the nitrate plants, the dam was started during a war-time period of maximum prices and minimum efficiency of labor, and since the total cost of the dam, equipped with 125,000 hp., was estimated in normal times to be $14,500,000, it is reasonable to say that the actual normal value of the work done is probably not over 50 per cent of the $17,000,000, or about $8,500,000. The United States engineers, after careful studies extending over several years, reported that the amount chargeable to navigation on a pre-war basis of cost was $8,575,000. The record therefore indicates that the value of the work done to date is an approximate measure of the amount which should be charged to navigation. Through the operation of the Ford amortization fund, however, if the money is placed at only 4½ per cent, the table given by the Secretary of War shows that the resulting fund would repay to the government not only the entire cost of completing the project but the full amount of the present $17,000,000 investment as well, the total amount returned being $70,100,000.

The Question of an Amortization Fund

It has also been contended that the government could not administer an amortization fund and that it does not do so. The administration of a sinking fund is nothing new to the federal government. The act of Feb. 25, 1862, provided that all duties on imported goods shall be paid in coin, and that the coin so paid should be set apart as a special fund known as a sinking fund which, together with the interest on the same, should be applied to the purchase or payment of the public debt as the Secretary of the Treasury should from time to time direct. The operation of a sinking fund in a long-time contract such as the Ford offer proposes can secure the most valuable results, and should be adopted. This fund, through the Federal Reserve Board and the Farm Loan Bank systems, should be placed at not less than 4½ per cent. If the fund was to be placed today, it could be placed in farm loan bonds at 5 per cent.

Senator McKinley Argues the Other Side of the Case

Complying with a request from Gray Silver, the Washington representative of the Farm Bureau Federation, Senator McKinley of Illinois has reduced to writing his arguments against the acceptance of the Ford offer. Senator McKinley's letteer was inserted in the *Congressional Record* of July 31. The opinion was expressed on Capitol Hill that the McKinley argument is much more likely to be effective than some of those which are less dispassionate. The text of the McKinley letter is in part as follows:

Government Deprived of Revenue

> The testimony of the United States engineers who are in charge at Muscle Shoals shows that with the auxiliary steam power which the government has bought and paid for and which it is proposed to give Mr. Ford 200,000 hp. can be depended upon for practically every day in the year and an additional 150,000 to 200,000 hp. for 10 months in the year. Under the present standard of electrical art this power can be distributed to towns and cities, mines, and manufacturing plants covering a circle of 600 miles in diameter, thus providing untold advantages for a very large section of the United States. Power of this kind delivered from Keokuk over parts of the western and southern Illinois sells at the dam for about $40 per horsepower per year which would mean a revenue to the government for the Muscle Shoals power of not less than eight or ten million dollars per year if the government should sell same to a distributing company at same price. This is figured on a basis of about one-half of 1 cent per kilowatt-hour.
>
> One objection I have to Mr. Ford taking over this power under his present plan is because he proposes to deprive thousands and thousands of people over an area of 600 miles in diameter of power and its use in order that he may build up at Muscle Shoals a new Detroit. That is a fine thing for the inhabitants of Muscle Shoals, and naturally they are extremely desirous of seeing their real estate advance in value from $50 per acre to $10,000 an acre, but it is a bad thing for the thousands and thousands of people within this 600-mile area. This power which will wholesale at $10,000,000 per year will retail for over $50,000,000 per year. Mr. Ford proposes to buy from the government for $5,000,000 what has cost the government $150,000,000 and pay 4 per cent interest on the additional forty or fifty million dollars which the government must invest to complete the dams, and in addition to that he proposes to pay the government $46,000 a year, which he calls amortizement, and $55,000 a year which he calls repairs.

Repairs to Cost More Than Ford Allows

> The testimony of the army engineers is that the repairs at the dams will be about $227,000 a year, and not $55,000 a year. As Mr. Ford is to have the benefits if he gets this property on his terms and is to have these benefits for 100 years, he certainly, instead of offering to pay $55,000 a year, ought to agree to keep the dam in repair, which the army engineers say will cost $227,000 a year.
>
> Mr. Ford does not propose to take the property, but to have a $10,000,000 corporation take title to it, and this title stands for 100 years. The experience with all large capital investments as corporations is that sooner or later within 10 or 20 years, they pass into control of large money holders commonly known as "Wall Street." Mr. Ford, if he secures this property, gets the property tax free for 100 years with no control of any kind as to what price he should charge for power. He requires the government to install, at government cost, machinery for 850,000 hp. and agrees to use 100,000 of this power to make 40,000 tons of ammonia, which would make an amount of fertilizer which would not be sufficient to fertilize one-third of the acreage of Illinois alone, not including any other state, and he only agrees to furnish this provided he can sell at a profit of 8 per cent on the per cent interest money he has secured from the government. The testimony of the army engineers who have had this property in charge since its inception is that with Chilean nitrate or ammonia made from the byproducts of coke ovens, power must be secured at three-quarters of a mill per kilowatt. They further testify that, not getting any interest on the money the government has already invested, and 4 per cent on the additional money which the government must invest under Mr. Ford's offer, it would cost 2½ mills per kilowatt to generate the power, or three times, as much as they testify that power must necessarily be provided in order to compete with present fertilizer.

Alpha Chi Sigma to Banquet During Exposition Week

Members of the chemical fraternity Alpha Chi Sigma have arranged to get together during the week of the Eighth National Exposition of Chemical Industries in New York City. Dinner will be held at 6:30 p.m., Thursday, Sept. 14, at Keen's Chop House, 107 West 44th St., New York City. In view of the fact that many members of the fraternity will be in New York attending the exposition, a large dinner gathering is expected.

Canadian Paper Co. Ordered S

Justice Morrison has ordered the s on Oct. 13 of the Prince Rupert P & Paper Co., and has appointed S. Hyatt receiver for the bondholders creditors. Mr. Hyatt has been thorized to borrow $10,000 to license fees and taxes. The comp passed the payment of interest on first mortgage debentures on Jan. 1 on July 1.

Personal

Prof. CHARLES S. BISSON has left the South Dakota School of Mines to take charge of the department of chemistry at the Northern Branch of the University of California, Davis, Calif.

G. G. CREWSON has resigned the plant managership of the Refractory Products Corporation's plant at Index, Va., to become associated with the engineering staff of the National Aniline & Chemical Co., Buffalo, N. Y.

EDWARD J. P. FISHER, metallurgical engineer, formerly with the Atlas Die-Casting Co., Worcester, Mass., is now with the Edison Lamp Works of the General Electric Co., at Harrison, N. J.

F. B. FOLEY has been transferred by the Bureau of Mines from its Minneapolis station to the station at Rolla, Mo. At his new location Mr. Foley will continue active experimental work on the production and heat-treatment of drill steels.

CARL E. JULIHN, who has been superintendent of the Bureau of Mines station at Minneapolis, has been transferred to Washington, where he will serve on the technical staff of the War Minerals Relief Commission for the coming fiscal year. In the absence of Mr. Julihn, T. L. JOSEPH is acting as superintendent of the Minneapolis station.

D. H. KILLEFFER, on the editorial staff of *Drug and Chemical Markets*, will, on Sept. 1, be the New York editor of the *Journal of Industrial and Engineering Chemistry*, succeeding R. T. Stokes.

MENGO L. MORGENTHAU of 431 Hudson St., New York, has presented to Prof. W. L. Estabrooke for use at the College of the City of New York, especially in connection with Dr. Estabrooke's courses in inorganic chemistry, a collection of over fifteen hundred minerals, valued at $25,000. The collection is beautifully incased and electrically lighted. It has been placed in the entrance hall of the chemistry building, now called Baskerville Hall in honor of the late Charles Baskerville, director of the department of chemistry 1904-1922. Mr. Morgenthau is a member of the class of 1874.

A. A. MURPHY has been appointed resident sales manager of the industrial and railway paint and varnish division of E. I. du Pont de Nemours & Co., with headquarters at New York.

C. J. MURPHY, vice-president of the Phoenix Leather Co., Pittsburgh, Pa., has resigned, effective Aug. 1, to become connected with the Deford Co., Baltimore, Md.

Dr. ROLAND P. SOULE, a graduate of the department of chemical engineering, Columbia University, has accepted a position with the Combustion Utilities Corporation, 24 State St., New York.

Among the notable additions to the Federated American Engineering Societies is the Engineers Club of Columbus, Ohio, which has appointed Prof. James R. Withrow of Ohio State University as its representative on the American Engineering Council, the executive organ of the federation. Professor Withrow will serve until Jan. 1, 1924.

Obituary

JOSIAH MONROE, for many years secretary and treasurer of the Juragua Iron Co., with plant in Cuba, died at his residence, Philadelphia, Pa., on July 26, following an illness of several weeks, at the age of 70 years. He is survived by his wife and a daughter.

CHARLES ADAMS PATTERSON, vice-president of E. I. du Pont de Nemours & Co., died on July 26 at the Presbyterian Hospital, Philadelphia. Mr. Patterson was taken to the hospital on July 10 suffering with a carbuncle. An operation was performed and was apparently successful until a few days before his death, when complications set in and septic pneumonia developed.

Mr. Patterson's death came as a shock to a multitude of friends, for he was in the prime of life and of a sturdy constitution. His unfailing good humor, keen aggressiveness and wholesome conviviality made him a true friend to literally hundreds of persons with whom he dealt. Charles L. Reese, chemical director of the du Pont company, says of Mr. Patterson: "He was a lovable character and a staunch friend—probably the most popular man in the company."

Mr. Patterson had spent his entire business life in the explosives industry, which he entered as an office boy with the Repauno Chemical Co. in 1894. From that position he advanced rapidly until he had become one of the best known and most important men in the world of explosives manufacture.

He was born at Minersville, Pa., April 9, 1876, the son of the late George Patterson, onetime manager of the black powder operating department of the du Pont company.

Mr. Patterson was graduated from the Wilmington High School in 1894, and he immediately took his first office boy position with the Repauno company. His desire for advancement led him to study shorthand at night and he was soon made stenographer and clerk to the late H. M. Barksdale, at that time managing head of the Repauno company. In September, 1896, he was granted leave of absence to enter college and he became a student at the University of Pennsylvania, taking the chemical course, in which he was graduated in 1900. During his college years he spent the summer vacations working in various plants of the du Pont company, so that on his graduation he was remarkably well equipped for his lifelong work in the explosives industry.

Immediately after his graduation he was employed as a chemist at the Repauno works and 3 years later was made assistant superintendent. During the succeeding 6 years he was successively superintendent at the Forcite works, the Barksdale works and the Hercules works, returning in May, 1912, to the Repauno plant as its superintendent.

Mr. Patterson's experience and managerial ability played an important part in the rapid expansion of the du Pont company's activities during the war. In May, 1916, he was made general superintendent of the du Pont company's high explosives operating department and a year later became assistant director of the explosives manufacturing department. It soon became necessary for him to take on more responsibilities and he was made director of the explosives manufacturing department and a short time later was elected a member of the board of directors of the du Pont company.

After the armistice Mr. Patterson was chosen as a member of the executive committee, charged with the duty of readjusting the company's affairs to a peace-time basis. He was elected a vice-president and was given general supervision of the explosives manufacturing department, in which position he continued until September of last year, when he was elected as general manager of the explosives department, which had been enlarged to include not only manufacture but also sales and all other activities connected with this branch of the company's business. This new position threw upon him a greater burden of responsibility, as it gave him the entire management of a branch of the business almost as large as the company's whole organization in the years before the war.

Mr. Patterson was always interested in educational matters and was particularly devoted to the interests of the University of Pennsylvania. He was closely identified with civic movements and was deeply interested in political matters. He had been chairman of the Republican County Committee for 2 years and had taken an active interest in several national and state campaigns.

Irenée du Pont, president of the du Pont company, paid tribute to Mr. Patterson in the following words: "The company has lost a vice-president whose knowledge and judgment were extraordinary and whose energy and loyalty were an example to all of us. Even more than that, his lovable character made him the friend of substantially every employee and thereby contributed in no small degree to the esprit de corps which has meant so much to the success of the du Pont company."

WILLIAM ANDREW THOMPSON, JR., vice-president of the Texas Co., New York, died suddenly on July 24, at his residence, 282 East Seventeenth St., Brooklyn, N. Y., aged 50 years. He was in charge of the export, marine and northern sales departments of the company.

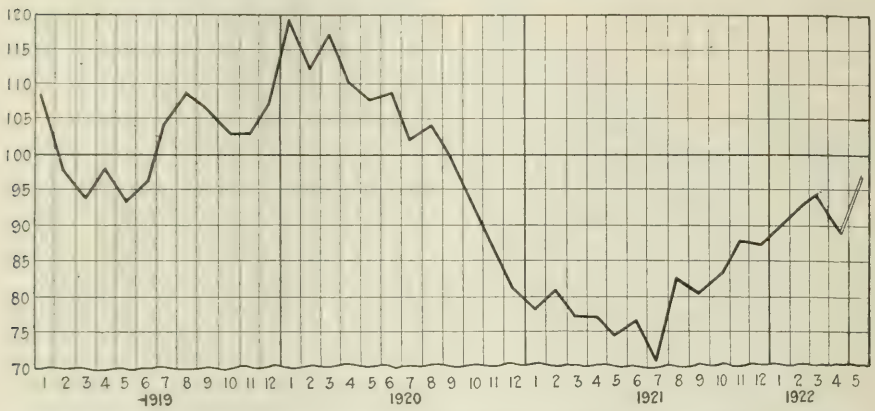
Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

The Trend of Production in the Chemical and Allied Industries

A Few Statistical High-Spots Along the Business Horizon—Manufacture in Some Lines Increasing in Spite of Strikes—Record Set by Paper and Rubber Industries



THE HARVARD ADJUSTED INDEX OF THE VOLUME OF MANUFACTURE. (*NORMAL = 100*)

AS LATER STATISTICS of production are becoming available for the chemically controlled industries it is increasingly evident that the improvement noted during earlier months has been of a very general nature. Few if any of these basic industries have failed to respond to the stimulus of better times. Even at present in the face of strikes which threaten serious fuel and transportation shortages it is encouraging to know that the progress of production in certain lines continues practically without interruption. This demonstrates clearly the inherent strength of the present position of industry. The Harvard Service's adjusted volume index is gradually approaching the normal of 100, which is an average value determined on the basis of production in good and bad years and in which both seasonal influences and long-time tendencies have been considered. This index, which had risen to 93.7 in March, fell to 90.1 in April, but in May arose to 96.0—the highest point to be reached in the present movement.

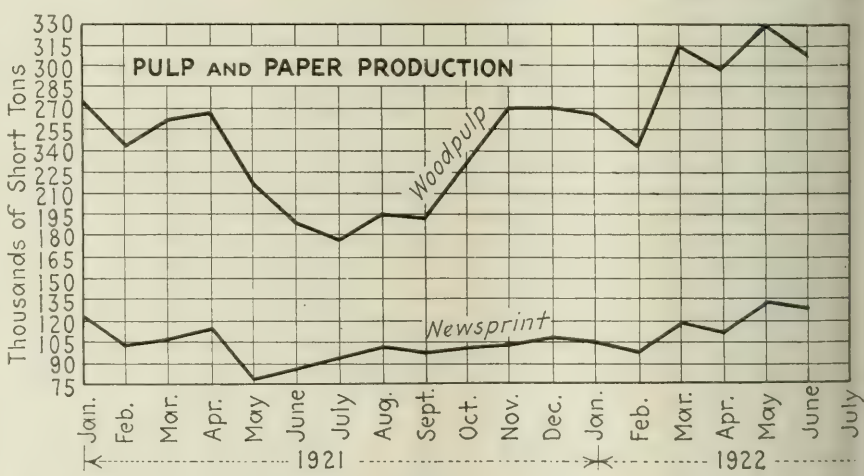
PAPER AND RUBBER INDUSTRIES SET RECORDS

Among the high-spots in production which have not already received comment on these pages is the paper situation. The output in May was the highest point which has been reached since 1920. As measured by the Harvard index, production had attained a value of 99.2 per cent of normal. In June there was a slight recession. Newsprint produced in that month was 127,230 net tons, as compared with 87,724 tons in June, 1921, and 114,440 tons as the 5-year average for that month. The total for all grades of wood pulp for June was 313,259 net tons, while the corresponding figure for last year was but 189,389 tons.

According to recent news from Akron, July will stand out as the month of greatest tire production for that district. Over two and a half million tires were produced in Akron tire plants during the month, as compared with a total in May for the entire country of 2,722,000. In the preceding month the total output had been 2,421,000 tires. The imports of crude rubber during the first 5 months of the current year show an increase of 112.4 per cent over the receipts of the corresponding period in 1921.

Notwithstanding the several recent cuts in the price of crude oil as well as the accumulation of vast stocks of oil and of various petroleum products, production during June continued at an even greater rate than in the record month of March, 1922. The daily average reported by the Geological Survey was 1,508,233 bbl. for June and 1,504,323 bbl. for March. The total output in June, however, was about a million barrels less than in either March or May.

Other production and consumption statistics for the chemical and allied industries may be found in Table I. These are taken from the "Trend of Business Movements" section of the *Survey of Current Business* which is being compiled through the co-operative work of the Bureaus of Standards,



PULP AND PAPER PRODUCTION, BY MONTHS, JANUARY, 1921, TO JUNE, 1922

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	152.08
Last week	153.56
August, 1921	158
August, 1920	264
April, 1918 (high)	286
April, 1921 (low)	140

For over a month this index number has shown a consistent decline, having now fallen more than 8 points below the maximum of 160.49 reached during the week of May 24. This week's recession is traceable principally to the much lower prices for cottonseed and linseed oils.

ABLE I—THE TREND OF PRODUCTION IN CERTAIN OF THE CHEMICAL AND RELATED INDUSTRIES

* Shipments from Minneapolis. † Includes January and February only. ‡ Consumption by tire manufacturers.

ensus and Foreign and Domestic ommerce. It is to be regretted that few of the strictly chemical industies are represented in this worthhile compilation. At present the ood chemical manufacturers are practally the only branch of the chemical dustry whose production is reported the Commerce Department.

As an important index of industrial ogress it is of interest to note that the twenty-three commodities inuded in Table I, nineteen showed ineases over 1921. The only decreases re in the case of bee-hive coke, cotnseed and linseed oils and copper etal.

The New York Market

NEW YORK, Aug. 7, 1922.

The possibilities of an acute fuel ortage has doubtless been responsie for the much livelier interest which e chemical market has shown in ny of the more basic commodities. a few instances producers have alady advanced their quotations, prenably in anticipation of fuel and nsportation difficulties. An addinal factor which has stimulated pment business, especially among porters, has been the news from ashington that an agreement was ely to be reached on the tariff. In ll-informed circles, however, it is nerally believed that the tariff bill l not become a law much before t. 1.

Bichromates of potash and soda have own appreciable increases during the erval and a much better inquiry was orted by several producers. Imcters of powdered white arsenic have own considerable firmness in their otations, although domestic factors ve not altered former prices. Cop- sulphate continues along the same n lines recently reported. Oxalic acid was in light supply on spot and several producers named higher prices for shipment. Caustic soda for export showed very little change, but domestic material was in steady demand for fair-sized quantities. Yellow prussiate of potash showed effects of renewed activity at slightly higher levels. Sulphate of ammonia remained in very light supply, with the export demand rather brisk. Zinc chloride prices were recorded at slightly lower levels and imported white granular sal ammoniac was considerably lower on spot, due to the recent importations.

General and Special Chemicals

Arsenic—A good inquiry was reported among resale merchants, with several fair-sized orders transacted at 8c. per lb. Domestic factors have not altered former prices of 7½c. The insecticide industry continues to show considerable activity.

Barium Chloride—Material was offered at $85@$90 per ton on spot, with shipments from abroad held around $82 per ton. The demand has slackened noticeably.

Bichromate of Soda—Spot goods among resellers were higher at 7½@8c. per lb. Large producers have also advanced quotations and name 7½c. as a low figure. The fuel shortage and export demand are responsible for the advance.

Bichromate of Potash — Producers were quoting 10½c. per lb., showing an advance of 1c. per lb. Smaller lots are bringing as high as 11c. per lb. Fuel conditions are also the cause of the increase in this commodity.

Caustic Potash—Prices have shown very little change during the past few weeks. General conditions are rather quiet, with prices ranging around $5.60 @$6 per 100 lb.

Caustic Soda—There has been no unusual feature reported in the export market during the week. A few odd lots were sold around $3.50 per 100 lb. f.a.s. Domestic goods were in moderate demand at $3.75 per 100 lb., exstore. Contracts remain quotably unchanged.

Fluoride of Soda—There has been keen competition among resellers, with sales recorded as low as 9c. per lb. Domestic factors quote the market at 9½c. per lb. The demand has been fairly active for small lots.

Formaldehyde—Small-quantity purchases featured the market during the past week, with sales heard around 8@8½c. per lb. Goods were not as freely offered as reported a few weeks ago and competition was less keen.

Glaubers Salt—Domestic producers continue to quote $1.25 per 100 lb. in bags and $1.40 in barrels. Imported goods in barrels brought as low as 95c. per 100 lb. The demand is rather dull at present.

Nickel Salts—Manufacturers have announced an advance of ½c. per lb. on the single variety, the present market for which is quoted around 12c. per lb. The double salt is held at around 11½c.

Oxalic Acid—A very firm tendency has been shown by this product during the interval, with prices ranging around 15c. per lb. f.o.b. works. Spot prices are quoted at 15½@16c. per lb.

Coal-Tar Products

The spot market for benzene was materially higher, although no change in former prices was reported. Water white solvent naphtha was reported higher among second hands and toluene, 90 per cent, was also much stronger on spot. Phenol is exceedingly scarce and dealers reported a very firm market. Technical beta naphthol has been offered rather freely of late, with prices fractionally lower, however.

Aniline Oil—Consumers have shown a better interest during the week and prices have been well maintained at 14@15c. per lb. Spot stocks are not as plentiful as recently reported.

Benzene—Spot supplies are very scarce and producers are finding difficulty to make regular contract deliveries. Contracts of the pure material were quoted at 30@35c. per gal. and 90 per cent at 27@32c. per gal. Dealers quote the resale market at 40@45c. per gal. for the 90 per cent.

Cresylic Acid—Consumers continue to send in a steady call for quantity shipments and the general market situation remains very firm. Sales of the 97-99 per cent for shipment were reported at 56@58c. per gal., with the 95-97 per cent at 51@53c. per gal. The spot resale market for 97-99 per cent held around 65c. per gal. and 62c. per gal. for the 95-97 per cent.

Phenol—There has been a very strong demand during the past few weeks, with the prime U.S.P. material in very scanty supply. A few odd lots were reported sold up to 17c. per lb. The general range is around 15@16c. per lb.

Hercules Earnings Four Times Those of 1921

For the 6 months ended June 30 the Hercules Powder Co. shows net earnings of $717,326. After subtracting charges, taxes and preferred dividends this is equivalent to $5.50 a share on the $7,150,000 common stock. This compares with earnings of $103,009, or $1.37 a share, for the corresponding period of 1921. This is shown in the following statement of income during the first half of each of the last 4 years:

	1922	1921	1920	1919
Gross receipts	$7,978,201	$6,537,615	$9,683,942	$12,173,831
Net earnings	717,326	103,009	1,265,285	488,420
Pref. dividends	324,051	253,154	190,582	187,250
Surplus	$393,275	$150,145 (a)	$1,074,703	$301,170

(a) Deficit.

The consolidated balance sheet on June 30, 1922, follows:

Assets	
Property and plants	$22,635,431
Cash	1,606,860
Accounts receivable	3,039,519
Collateral loans	2,028,019
Investment securities	1,874,676
Liberty bonds	1,172,239
Supplies	2,877,315
Finished products	1,950,105
Deferred charges	82,704
Contingent assets	146,268
Total	$37,413,136
Liabilities	
Common stock	$7,150,000
Preferred stock	8,112,900
Preferred stock in escrow	1,350,000
Aetna bonds	3,891,475
Bills payable	42,960
Accounts payable	293,266
Preferred dividends	82,800
Deferred credits	34,911
Federal taxes	88,898
Reserves	1,893,287
Contingent liabilities	146,268
Profit and loss surplus	14,326,371
Total	$37,413,136

Allied Chemical & Dye Active on Stock Market

Rumors that the dividend rate on the common stock of the Allied Chemical & Dye Corporation was shortly to be increased from $4 to $6 per year were largely responsible for sending this stock up to 74½ on Aug. 1. This was a new high for the year and is particularly significant, since it came in the face of the Senate's recent unfavorable action on the dye embargo.

No statement has been made by officials of the company regarding either dividends or earnings, but it is generally believed that current earnings after preferred dividends and taxes are at the rate of over $8 a share on outstanding common stock.

Air Reduction Co.'s Profits in Second Quarter, 1922

The operations of the Air Reduction Co., Inc., for the second quarter of 1922 show net profits of $231,351.25 before deduction is made for federal taxes. The gross income for the period was $1,773,882.89 and the operating expenses amounted to $1,235,004.67.

The operating income of $538,878.22 was divided between $270,585.72 of additions to reserves, $36,941.25 for paid and accrued bond and mortgage interest and the net profits referred to above. On the outstanding stock of 153,114 shares of no par value, the earnings are equivalent to $1.50 per share.

Exports of Chemicals

A special compilation of exports of domestic merchandise has been prepared by the Bureau of Foreign and Domestic Commerce for the Finance Committee of the Senate to use in connection with its study of the tariff. The report shows the value of all exports of chemicals to have been as follows:

1918	$165,239,860
1919	133,739,066
1920	168,999,706
1921	61,111,410

Exports to certain countries were as follows:

	1918	1920	1921
France	$35,624,663	$7,952,707	$2,740,229
Italy	13,687,087	5,336,540	603,273
England	24,819,739	19,759,556	8,888,363
Canada	26,682,349	20,790,637	11,989,648
Japan	16,643,052	21,943,000	5,238,540

Some of the totals for chemicals exported during 1920 and 1921 are as follows:

Article and	Unit	1920	1921
Carbolic acid,	lb.	2,151,475	249,658
Nitric acid,	lb.	716,914	177,580
Sulphuric acid,	lb.	28,987,342	12,814,344
Wood alcohol,	gal.	703,064	412,110
Calcium carbide,	lb.	23,369,534	11,808,252
Benzene,	lb.	13,174,268	72,030,400
Copper sulphate,	lb.	3,783,409	3,582,933
Aniline dyes,	dollars	22,450,480	5,067,000
Formaldehyde,	dollars	2,640,225	349,089
Glycerine,	lb.	1,742,708	2,394,714
Acetate of lime,	lb.	23,309,469	18,239,740
Chloride of lime,	lb.	48,826,348	18,447,579
Bicarb'nate of soda	lb.	20,642,201	11,703,183
Caustic soda,	lb.	224,137,406	49,865,219
Sal soda,	lb.	12,030,193	10,354,513
Silicate of soda,	lb.	34,095,542	20,789,095
Soda ash,	lb.	166,761,603	35,042,791
Borax,	lb.	14,325,037	4,061,633

Cottonseed Products During 1921 and 1922

Production, stocks and shipments of various cottonseed products for the 11 months' period ended June 30, 1921 and 1922, are compared in the following tabulation of the Census Bureau:

Export and Import Figures Show Trend of Chemical Business

Exports of chemicals and allied products declined from $10,424,794 in May to $8,662,326 in June. There was an increase as compared with exports in June of 1921, when the total value was $7,106,802. Exports of fertilizers in June were less than one-half those in May. Exports of explosives were only slightly more than one-third of those of May. Paints, pigments and varnishes almost held their own. Some comparisons between exports in June 1922, with those of June, 1921, are as follows:

	1921	1922
Benzene, lb.	5,839,131	6,713,57
Carbolic acid, lb.	116,846	4,61
Acetic acid, lb.	817,159	2,481,29
Wood alcohol, gal.	24,036	63,93
Ammonium sulphate, lb.	261,725	217,28
Copper sulphate, lb.	55,020	291,27
Cyanide of soda, lb.	165,563	1,633,60
Soda ash, lb.	4,259,695	1,898,90
Caustic soda, lb.	3,239,833	11,355,90

Imports of chemicals on the free lis during June were valued at $6,815,381 Imports of dutiable chemicals in Jun were valued at $4,429,532. While th imports of free-list chemicals show a increase of about $400,000 over those o June, 1921, there was a falling off o nearly $600,000 as compared with im ports in May.

There was a decided upturn in th imports of dutiable chemicals, doubt less in anticipation of tariff legislation The June imports of dutiable chemical were nearly one million and a hal dollars greater than those in May an exceeded those of June, 1921, by nearl $2,000,000.

The value of coal-tar products im ported during June was $1,455,345, a compared with $817,364 in June o 1921. A comparison of other import is given in the following table:

	1921	1922
Calcium acetate, etc., lb.	3,728,670	6,546,8
Quinine, oz.	70,700	132,3
Carbonate of potash, lb.	359,232	673,4
Cyanide of soda, lb.	3,295,887	519,9
Nitrate of soda, tons	37,847	49,4

As compared with last year, th greatest increases came in the gu group. More than $1,000,000 wort of gums was imported during Jun than in June of 1921. The imports o copal in June amounted to 3,597,596 l Receipts of gum arabic amounted t 1,338,286 lb. Actual camphor import totaled 208,675 lb.

COTTONSEED PRODUCTS MANUFACTURED, SHIPPED OUT AND ON HAND

Item	Year	On Hand Aug. 1	Produced Aug. 1 to June 30	Shipped out Aug. 1 to June 30	On Hand June 30
Crude oil, lb.	1922	18,762,794*	922,790,186	922,739,461	12,193,69
	1921	22,620,357	1,285,626,797	1,278,151,580	37,299,21
Refined oil, lb.	1922	228,263,633†	831,952,028‡	.....	211,070,22

	1921	18,304	1,234,573	1,164,021	88,85
Linters, 500-lb. bales	1922	124,377	394,004	449,760	68,62
	1921	176,316	434,239	456,333	154,22
Hull fiber, 500-lb. bales	1922	30,676	42,123	33,132	39,66
	1921	150,659	87,223	117,624	120,25

* Includes 4,346,848 and 1,272,420 lb. held by refining and manufacturing establishments and 5,507,8 and 1,962,480 lb. in transit to refiners and consumers Aug. 1 and June 30, respectively.

† Includes 5,884,495 and 4,229,584 lb. held by refiners, brokers, agents and warehousemen at places oth than refineries and manufacturing establishments and 7,969,713 and 5,377,083 lb. in transit to manufactur of lard substitute, oleomargarine, soap, etc., Aug. 1 and June 30, respectively.

‡ Produced from 903,708,168 lb. crude oil.

The St. Louis Market

ST. LOUIS, MO., Aug. 3, 1922.

Trading conditions in this market for chemicals have undergone no change since our last report. The market has felt very little effect of the coal shortage or transportation difficulties, but there is a tendency to rush shipments of some commodities in the hope of avoiding a tie-up should the situation become more serious. One of the outstanding features for the past 2 weeks has been the steadiness of prices in spite of the present unsettled situation. Business for the month of July has been much better than for the corresponding month of last year, and has by far exceeded the preceding month of June, with a continued broadening of inquiries indicating that confidence is again being restored.

ALKALIS

The market on alkalis has been very steady. No price changes have been reported and practically nothing except routine business is being done. *Soda ash* can be placed in the same classification with *caustic* in regard to price and volume of business. *Bicarbonate of soda* is moving fairly well and prices remain firm, with all dealers bringing their prices in line with the top market. *Sal soda* is moving rather slowly and jobbers are carrying very small stocks during the hot weather.

GENERAL AND SPECIAL CHEMICALS

Heavy mineral acids continue to move at the same rate. *Acetone* has again been advanced on account of the increase in *acetate of lime*, and is now being quoted at 13c. in carlots and 14½c. in less than carlots in drums, f.o.b. producers' works. Some of the leading producers of *acetic acid* have announced their new prices based on acetate of lime at $2.35 per 100 lb. This is the second advance in acetic acid as well as acetate of lime since the first of July. The demand for *citric acid* has been along quiet lines and the spot market is liberally supplied. Makers of *oxalic acid* are now quoting 16¾@17c. with a curtailment of supplies, and buyers are finding it difficult to locate spot goods. Supplies of *ammonia water*, 26 deg., are very large with an erratic demand. The market for *white arsenic, powdered*, is much stronger today than it was in our last report, prices now being quoted at 7½@7¾c. f.o.b. New York. The demand for *carbon bisulphide technical* has not eased since our last report and prices remain very firm. *Carbon tetrachloride* is moving in a routine way and is now being quoted at 9c. f.o.b. New York in large drums. *Glycerine* is steadily advancing and spot goods are now being held at 16c. per lb. There are no surplus stocks, the market being completely in the hands of producers. *Sulphur* has moved rather briskly due to consumers trying to anticipate the railroad strike. Prices did not change and business is again of normal volume. *Zinc sulphate* is still very strong at $2.85 per 100 lb. carlots f.o.b. St. Louis, and is keeping in line with the spelter market, which is now around $5.80 per 100 lb. with a further advance expected at any time.

VEGETABLE OILS AND NAVAL STORES

Turpentine is still the wild Indian of the naval stores. It has run prices up and down and is today anchored at $1.27 in single barrels, 6c. higher than when last reported. *Linseed oil* is running the usual course for this season. No contract business is being done, and only the necessary daily requirements are in demand. *Castor oil* remains firm and in good demand. Price is 13¼c. in drums for quantities of 200 gal., ½c. advance for less quantities. Further advances in castor would not come as a surprise.

PAINT MATERIAL

The month of August is a continuation of the dull period in the paint trade. Only routine buying is being done at present. Railroads are not buying and this curtails almost the entire business of several grinders in this district. Shipments of supplies are not coming through as they should and this too holds up operations.

The Iron and Steel Market

PITTSBURGH, Aug. 4, 1922.

Production of pig iron and steel has not decreased as much as was feared when railroad congestion due to the shopmen's strike increased the scarcity of coal. Production in July was approximately equal to production in May and June and thus was greater than in any earlier month of the year. As matters now stand, it is practically certain that production in August will show a great decline, but it does not follow that this will cause steel to become scarce. During the 4 months since the coal strike started there has been heavy production of steel, at a rate 20 per cent above the rate in the two biggest tonnage years before the war. In February, March and April it was commonly believed that part of the buying of steel was by way of insurance against a possible curtailment of production by the coal strike. If there was anything in that theory, steel consumers are more or less fortified. It is no small thing for the steel industry to run for 4 months at the rate of producing 36,000,000 tons of ingots a year. The two war years, 1917 and 1918, showed production between 43,000,000 and 44,000,000 tons, and the first 9 months of 1920, when consumption appeared to be very heavy, showed a rate of 42,000,000 tons.

STEEL INDUSTRY KEEPING AHEAD OF THE STRIKES

The fact that most buyers are pressing mills for better deliveries and the further fact that there is some inquiry for finished steel products for early delivery at premium prices are not conclusive that steel is going to become genuinely scarce. Consumers know that mills are well sold up ahead, and the individual consumer may be exerting pressure in fear that otherwise he may not receive his quota. The payment of delivery premiums involves only a relatively small tonnage. Finally, it is inconceivable that when the steel mills have been able to run so well during 4 months of the coal strike a fuel or transportation condition could arise that would greatly restrict the production of steel without also interfering very decidedly with the consumption of steel. The steel trade, taking it as a whole, possibly stands in less danger of steel becoming inconveniently scarce than it does of jobbers and manufacturing consumers being seized with a liquidating fever when coal and transportation conditions eventually begin to approach normal.

The turnover in steel products in the open market has become lighter still. The fact in itself is not significant, for the market is now in the middle of the midsummer period, always a dull one in steel. As to forward deliveries, the mills are not in position to sell, as they are already well sold up and farther ahead than they thought since production promises to be lighter than expected. While the mills would be unwilling to sell, buyers are unwilling to buy, and the habits of the market are too well known for anyone to expect buyers to become more willing to buy merely from seeing, later, that steel is more readily obtainable.

STEEL, IRON AND COKE PRICES

Basis prices, for deferred delivery, are substantially unchanged, at 1.70c. for bars, shapes, plates, 3.15c. for sheets, and so on, but the prices are in some cases more or less nominal, there being little trading.

For early deliveries limited tonnages are available at premiums ranging roughly speaking from $2 to $5 a ton. The demand is rather limited in point of tonnage, but the balance is somewhat in favor of sellers, so that delivery premiums show a slight tendency to increase.

The coal market means little to the iron and steel industry, prices being high while tonnages available are limited. Connellsville steam coal reached a new high point of $8.50 on Wednesday, July 26, and then reacted sharply to $6 Tuesday morning, Aug. 1, by reason of withdrawal of buyers. On the reappearance of buyers the market has since advanced to $7. Connellsville coke, which is so scarce and at such high prices as to interest practically no consumers but foundries, advanced to $15.50 for foundry grade at the beginning of this week, having since softened a trifle.

Merchant production of pig iron has decreased greatly and is now quite light. There are some stocks at furnaces and some consumers have very fair stocks, while it appears that consumption has been decreasing. Offerings are very limited, as is also demand, but the latter preponderates and prices have been rising.

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

PAPER—The Chesapeake Paper Board Co., Baltimore, Md., has placed its plant on the Key Highway on a maximum production basis, under 24-hour operation, giving employment to a full working force. The output is averaging about 60,000 lb. of material per day.

The Clarion Paper Co., Johnsonburg, Pa., is operating its local mill on a full production basis, giving employment to a regular working force.

The International Paper Co., New York, N. Y., is increasing production at its newsprint plants, and is now averaging in excess of its normal rated capacity of 1,300 tons per day. It is expected to maintain operations at close to this basis.

OIL—The Midcontinent Producing & Refining Corp. is perfecting plans for the resumption of operations at its oil refinery at Greenville, Tex., comprising the former plant of the North Texas Oil & Refining Co., recently acquired. Improvements will be made in the refinery, and regular working force employed.

The oil refinery of the Beaver Elcctra Refining Co., Electra, near Wichita Falls, Tex., will be placed in operation by the new owners, D. E. DeCourse and associates, who recently purchased the plant. It is expected to develop normal capacity at an early date. Improvements are being made.

The Pure Oil Co. and the Humphreys Oil Co., Mexia, Tex., affiliated, are increasing production at their local properties.

IRON AND STEEL—The Iron Products Corp., Birmingham, Ala., is operating full at all its plants with the exception of the blast furnace at Holt, Ala.; it is expected to blow in this unit during the present month.

The Crucible Steel Co. is increasing production at its plant at Syracuse, N. Y. The works have been on a curtailed operating basis for about 18 months past. Other plants of the company are also advancing their outputs, including the works at Pittsburgh, Pa., and Harrison, N. J., and it is expected to operate at normal at an early date.

Coal shortage and the railroad strike have been responsible for the partial shutdown of a number of steel mills during the past week, as well as the banking of certain blast furnaces, as follows: The A. M. Byers Co., Pittsburgh, Pa., has curtailed operations at 21 puddling furnaces at Girard, O.; the Briar Hill Steel Co., Youngstown, O., has banked a second furnace, leaving but one active unit at the works; the Fort Wayne Rolling Mills, Fort Wayne, Ind., has closed its plant for an indefinite period; the American Sheet & Tin Plate Co., Youngstown, O., has shut down temporarily 26 tin mills, with expectation of resuming at an early date; the Buffalo-Union Furnace Co., Buffalo, N. Y., has banked one of its furnaces, and the Doner Steel Co., in the same district, has also closed down a blast furnace at its works; the Follansbee Brothers Co., Pittsburgh, Pa., has closed down its sheet and tinplate mills temporarily at Steubenville, O., and Follansbee, W. Va., affecting about 2,000 men; the American Sheet & Tinplate Co., a subsidiary of the United States Steel Corp., has curtailed operations at a number of hot mills at its Farrell, Pa., works, with plans for resumption in the immediate future; the Shenango Furnace Co. has banked its furnace at Sharpsville, Pa.

In order to insure continuous operations at its steel mills the Central Iron & Steel Co., Harrisburg, Pa., has discontinued the use of coal as fuel at two of its open-hearth furnaces, and is now running on oil.

The Gulf States Steel Co., Birmingham, Ala., has all departments of its works in full operation, and is planning to increase production immediately at its finishing mills.

MISCELLANEOUS—The Stonecreek Brick Co., Stonecreek, O., has commenced operations at its local plant with all 8 kilns ready for service, on a working basis of 50,000 bricks per day.

The American Window Glass Co. has commenced preliminary operations at the No. 1 tank at its Kane, Pa., works; the No. 2 tank is in full operation and it is proposed to have the entire plant running at capacity before the close of the month. About 200 men will be added to the working force. The Interstate Window Glass Co., at this same place, is making ready to resume operations at its plant after a shutdown for about 90 days, and will give employment to about 250 operatives.

Owing to fuel shortage the Giant Portland Cement Co. has closed down temporarily its Central mill at Copley, Pa. Unless there is a change in the situation the company will soon curtail production at its Reliance mill in this same district.

The Summit Solvay Co., Birmingham, Ala., has placed its final battery of coke ovens in operation, making 240 ovens now in service, or full plant capacity. It is expected to operate on this basis for an indefinite period.

The American Brass Co., Waterbury, Conn., is increasing operations at its local mills, and is now consuming at the rate of more than 800,000 lb. of copper per day. The company is a subsidiary of the Anaconda Copper Mining Co.

The National Sulphur Co., Akron, O., is arranging for the immediate operation of its local plant and will recruit a working force of about 250 men.

The W. D. Byron & Sons Leather Co., Williamsport, Md., is running its local tannery at full capacity in all departments. A number of extensions will be made in the plant at an early date.

The Continental Leather Co., Wissimoming, Philadelphia, Pa., is maintaining active operations at good capacity at its local tannery.

Construction and Operation

California

OAKDALE—The Pacific Asbestos Corp., operating mining properties in this section, has preliminary plans under way for the construction of a new plant. Plans will be prepared at an early date. The company has recently been acquired by new interests headed by W. A. Sutherland, president of the Fidelity Trust & Savings Bank, Fresno.

LINDSAY—The Big Fertilizer Co. is negotiating with the local Chamber of Commerce relative to a site for the construction of a new plant for the manufacture of commercial fertilizer products. The initial works will cost about $25,000. George W. Abel is president of the company; A. M. Robertson, secretary of the Chamber of Commerce, is in charge of local details of the project.

MARYSVILLE—Local interests have organized a new company to construct and operate a plant for the manufacture of brick and other burned clay products. The initial works will have a capacity of about 10,000 bricks per day. Machinery will be purchased and operations placed under way at an early date. The company is headed by officials of the Shasta Lumber Co. and the Union Lumber Co.; L. E. Hite, L. A. Williams and Calvin Smith, all of Marysville.

SAN FRANCISCO—The Stauffer Chemical Co., 624 California St., manufacturer of sulphur products, etc., has tentative plans under consideration for the reconstruction of its building on Kearny St., recently destroyed by fire, with loss reported in excess of $75,000. The power house at the works was destroyed.

Florida

JACKSONVILLE—The Garage Equipment Co., 732 West Adams St., recently organized, is planning for the installation of machinery in a local building for the manufacture of chemical polishes, cements, and kindred specialties. L. P. Weathers is president; and O. T. Edwards, vice-president.

Georgia

ATLANTA—The Atlanta Glass Mfg. Co., recently organized with a capital of $500,000, has plans under way for the construction of a local plant for the manufacture of glass bottles, containers, etc. F. J. Cooledge, Jr., is president.

Idaho

SANDPOINT—The Lakeview Silver Mines Co., operating at the Conjecture mine, has tentative plans under consideration for the construction of a new concentrating mill, estimated to cost approximately $80,000.

Illinois

CHICAGO—Pratt & Lambert, Inc., 10 South LaSalle St., manufacturer of paints, varnishes, etc., has awarded a contract to P. J. & J. W. O'Connor, 189 West Madison St., for the construction of a 2-story addition to its plant, on North 26th St. near Princeton Ave., 50x150 ft., estimated to cost about $60,000.

ROCK ISLAND—The Service Rubber Co., 401 Central Trust Bldg., has commenced excavations for its proposed new 3-story plant on 2nd St., near 11th St., 60x300 ft., estimated to cost about $100,000, including equipment. Vervin & Horn, 311 Safety Bldg., are architects.

CHICAGO—The Swigart Paper Co., 653 South Wells St., has construction under way on a new 10-story and basement building at 715 South Wells St., 92x100 ft., to be used in connection with local operations, estimated to cost close to $500,000.

GRANITE CITY—The proposed new addition to be constructed at the local plant of the National Enameling & Stamping Co., estimated to cost about $1,500,000, will be used for increased production of coke and pig iron, and for the utilization of a greater number of byproducts from the coke ovens. The structures will include a coke-oven building, enlargement in blast furnaces, and extensions in the main steel plant, with new 3-story plate mill, 54x150 ft. Contract for the latter has been awarded to the St. Louis Structural Steel Co., National Bank of Commerce Bldg., St. Louis, Mo.

Indiana

GARY—The National Tube Co., Frick Bldg., Pittsburgh, Pa., has awarded a general contract to the Mellon-Stuart Co., Oliver Bldg., Pittsburgh, for the construction of its proposed new tube mill on the lake front at Gary. The works will consist of a number of furnaces with lap mills, butt mills and skelp mills, and are estimated to cost approximately $10,000,000, with machinery. The company is also perfecting plans for the early construction of a new battery of 140 coke ovens at this same location.

Kansas

LYONS—The Bevis Salt Co., Lyons, has plans under way for the construction of a new evaporating plant on local site, estimated to cost about $175,000, including equipment. A power house will be built and two electric turbines and auxiliary operating machinery installed.

Louisiana

SHREVEPORT—The Shreveport Brick & Tile Co. has acquired a tract of land on Douglass Island, comprising about 100 acres, as a site for the construction of a new plant for the manufacture of pressed brick and other burned clay products. The equipment installation will provide for an initial output of about 750,000 bricks per day. J. W. Peyton is president.

Maryland

BALTIMORE—The James Robertson Lead Works, Inc., 827 South Howard St., a subsidiary of the United Lead Co., 111 Broadway, New York, N. Y., has awarded a general contract to the Consolidated Engineering Co., 243 Calvert Bldg., Baltimore, for the construction of an addition to its plant on South Howard St. Charles E. McPhail is manager.

BALTIMORE—The White Co., 206 Water St., manufacturer of paints, varnishes, etc., has plans nearing completion for the construction of a 3-story addition to its plant to be equipped for general production.

BALTIMORE—The Maurice Chemical Co., 1427 Washington Blvd., D. E. Collins, president, recently organized, has plans under way for the establishment of a local plant to manufacture refractory and high-temperature furnace cements, and other products. A list of equipment to be installed is being prepared.

Michigan

PORT HURON—The Egyptian Portland Cement Co., Fenton, has leased the former

nops of the Grand Trunk Railway Co. ort Huron. Possession will be taken ce and the existing buildings remodeled mproved, and new machinery installed. planned to have the mill ready for ce early in the coming year.

AT ROCK—The Ford Motor Co., High-Park, will call for bids before the close e present month for the construction s proposed 1- and 2-story plant at Rock, for the manufacture of plate It is estimated to cost close to 0,000, with machinery. Albert Kahn, Marquette Bldg., Detroit, is architect.

Minnesota

PAUL — The Minnesota Wax Paper 1832 St. Anthony Ave., will commence mmediate construction of a new 1-story on Fairview Ave. near Roblyn St., ated to cost about $15,000.

Nevada

Y—The Nevada Consolidated Copper as plans in preparation for the rebuild-of its concentrating plant, known as fcGill concentrator, recently destroyed re with loss in excess of $1,000,000. new mill is estimated to cost approx-ely a like amount.

New Jersey

SEY CITY—The Robert Griffin Co., 151 field Ave., manufacturer of paper ucts, has filed plans for the erection of tory addition to its plant to cost about 00, exclusive of equipment.

ENTON — The Trent Tile Co., Klagg has awarded a contract to the N. A. K. ee Co., 206 East Hanover St., for the ion of a 1-story building at its plant, 56 ft.

ENTON—The Healey Bedson Pottery recently organized with a capital of 000, to manufacture sanitary ware, has ired property in Ewing Township, front-n the line of the Philadelphia & Read-Ry., and has plans under way for the ruction of a new plant. Work will be nenced at an early date. The company aded by Stephen J. Healey, Sr. and Jr., J. Harry Bedson, all of Trenton. Andrew ealey, 303 Washington Ave., Elizabeth, ., also an incorporator, represents the any.

WARK—The Essex Foundry, Murray anufacturer of iron castings, has com-ed the construction of a 1-story addi-84x110 ft.

New York

AMAPPAQUA—The F. W. Kraft & Sons Co., t Ave., Bronxville, N. Y., manufacturer ather products, has awarded a contract he Blaw-Knox Co., 30 East 42nd St., York, for the construction of a new ry tannery, 50x400 ft., at Chappaqua, nated to cost approximately $55,000. V. Kraft is president.

OCKPORT—The Lockport Foundries Corp. preliminary plans under way for the truction of a number of new buildings s plant. The capacity will be increased. ert E. Bryant is treasurer and general ager.

North Carolina

LTMORE—The Felstone Co., 326 Hay-l Bldg., Asheville, N. C., has completed s and will soon commence the construc-of a new plant at Biltmore, for the ufacture of ornamental concrete prod-The equipment installation will com-grinding and mixing machinery, ens. polishing apparatus, etc. The ini-structure will be 56x112 ft. C. Marshall Vatt is president.

SHEVILLE—The Southern Spar & Mica Haywood Bldg., has plans in progress the construction of an addition to its plant, for the manufacture of artificial ble products.

ILMINGTON—The City Council will soon nence the construction of a new filtra-plant at the municipal water works.

Ohio

KRON — The Falor Mfg. Co., recently nized, is arranging for the immediate ation of a new local plant for the ufacture of automobile tires and tubes, has leased the plant of the B. & W. ber Co. for its initial works. Machinery be installed at once to provide for an ut of about 2,000 tubes per day. Aaron r, formerly connected with the Good-Tire & Rubber Co., heads the organi-n.

EVELAND—The Otis Steel Co., Leader ., has arranged for the sale of bonds to mount of $5,000,000, a large portion he proceeds to be used for the construction of new plant additions. The extensions will include four open-hearth furnaces, sheet bar mill, blooming mill and strip mill, providing for an annual output of about 84,000 tons. It is planned to commence work at an early date, and have the structures ready for service late in 1923. G. Bartol is president.

Pennsylvania

PITTSBURGH—The Air Reduction Sales Co., 1100 Ridge St., manufacturer of commercial oxygen, acetylene, etc., has plans under way for the construction of an addition to its local plant. The company will also erect a new works on property acquired at Birmingham, Ala., to cost in excess of $200,000, with equipment, as well as an addition to its plant at Milwaukee, Wis. Headquarters are at 342 Madison Ave., New York, N. Y.

READING—The Consumers' Gas Co., Reading, has acquired property on Willow Grove Island, in the Schuylkill River, near the city, completing the acquisition of the entire island, and will use the tract for the construction of a new artificial gas manufacturing plant, utilizing bituminous coal as fuel, estimated to cost close to $1,000,000, with equipment. The company is a subsidiary of the United Gas Improvement Co., Broad and Arch Sts., Philadelphia.

ARNOLD—The American Window Glass Co. has preliminary plans under consideration for the rebuilding of the portion of its local glass manufacturing plant, including mechanical and other buildings, destroyed by fire, July 20, with loss in excess of $150,000, with equipment.

CLAIRTON—The Carnegie Steel Co. is said to be planning for the installation of a number of new batteries of byproduct coke ovens, totaling about 800 ovens in all, at its local plant. The project is estimated to cost in excess of $10,000,000.

LOCK HAVEN—The Borough Council has commenced the construction of a new chlorinating plant at the municipal water works. William T. M. Crowley, Pursley Bldg., Lock Haven, is engineer.

Texas

SISCO—The Sweetwater Cotton Oil Co., Sweetwater, Tex., has acquired the local plant of the Sisco Cotton Oil Co., and will take immediate possession of the property. The plant will be improved and operations commenced at an early date.

DALLAS—The Planters' Cotton Seed Products Co. has been organized with a capital of $100,000 to take over and operate the local plant of the Planters' Cotton Oil Co., recently acquired under bankruptcy proceedings. Extensions and improvements will be made and the mill placed in operation for the manufacture of cotton oil products, at an early date. E. L. Flippen, formerly vice-president of the last noted company, heads the new organization. Other officials are W. H. Jasson and Hugh E. Prather.

LAREDO—The Humble Oil Co. and the Pierce Oil Co., operating neighboring distributing plants, are planning for the rebuilding of the portions of their works destroyed by fire July 19, with loss estimated at close to $100,000, including equipment.

Virginia

WEBSTER — The Roanoke Brick Co., Roanoke, Va., has acquired the plant of the Roanoke Brick & Tile Corp. at Webster, and will take immediate possession. A number of improvements will be made to increase the present capacity of about 20,000 bricks per day. The purchasing company was organized recently with a capital of $100,000. W. W. Hobbie is general manager.

COVINGTON—The City Council will commence the immediate installation of a mechanical filtration plant at the municipal waterworks.

Wisconsin

PARK FALLS—The Flambeau Paper Co. has work under way on the rebuilding of its 2-story pulp and paper mill, recently destroyed by fire. The new structure will cost about $100,000, including equipment. Guy Waldo is general manager.

Washington

PRESCOTT—The Portland Flour Co. is reported to be planning for the rebuilding of its local mill, including power house and other mechanical departments, destroyed by fire July 22, with loss estimated at close to $1,000,000, with equipment.

Canada

FORT WILLIAM, ONT.—The Fort William Paper Co. is completing plans and will soon break ground for the construction of a new paper mill, adjoining its local wood pulp plant, estimated to cost about $1,500,000, including machinery. The local council has given the company authority to proceed with the work.

RICE LAKE, MAN.—The Gold Pan Mining Co. has preliminary plans under consideration for the rebuilding of the portion of its mill destroyed by fire July 19.

Mexico

TAMPICO — The Mexican Petroleum Co., Ltd., 120 Broadway, New York, N. Y., has commenced preliminary work for the construction of a new local oil-refining plant, estimated to cost about $2,000,000. A portion of the works will be given over to the production of gasoline, with equipment installation to provide for an output of about 800,000 gal. per day.

Industrial Notes

The Bethlehem Foundry & Machine Co., Bethlehem, Pa., announces that it has acquired all the capital stock, assets and equipment of the Wedge Mechanical Furnace Co. of Philadelphia. Henceforth the design, manufacture and sale of Wedge roasting furnaces will be conducted as a department of the Bethlehem Foundry & Machine Co., Bethlehem, Pa. All correspondence pertaining to roasting furnaces should be addressed to the Wedge Furnace Department of the company. Members of the operating staff of the Wedge Mechanical Furnace Co. have been retained, including Leslie H. Webb, whose services are available in a consulting capacity. The special facilities for laboratory, research and experimental roasting will also be continued. Inasmuch as the Bethlehem Foundry & Machine Co. has built these furnaces under contract for the Wedge Mechanical Furnace Co., it has all the necessary shop facilities to continue production on the same high plane that has characterized past performance. In brief, this change in ownership of the Wedge Mechanical Furnace Co. is no departure from past policies, service or product.

The American Gas Association has announced that its headquarters are located on the 18th floor of the Canadian Pacific Building, 342 Madison Ave., New York City. The telephone number at the new location is Murray Hill 4209.

The Conveyors' Corporation of America, Chicago, Ill. Announces that the Younglove Construction Co., United Bank Bldg., Sioux City, Iowa, has been appointed its representatives for the sale of American trolley carriers in northwestern Iowa, and in South Dakota. The American trolley carrier is equipment for handling coal from cars to storage pile or overhead silos by means of monorail and self dumping buckets.

The Electric Furnace Construction Co., 908 Chestnut Street, Philadelphia, manufacturers of electric furnaces, "Electro" steam boilers, etc., report an increase in capital and the appointment of the following new officers: P. H. Falter, vice-president and treasurer; Arthur G. Dickson, of Dickson, Beitler & McCouch, Philadelphia, vice-president and counsel and of the following new directors: John Gilbert, of Maderia, Hill & Co. William A. Webb, President Empire Coal Mining Co. T. H. Weisenburg. Frank Hodson retains the Presidency of the Company. P. H. Falter, the new vice-president and treasurer, is a graduate of the Engineering Department of the University of Michigan, and until recently has been vice-president and general manager of the Canadian Electro Products Co., at Shawinigan Falls, Quebec, a subsidiary of the Shawinigan Water & Power Co. Prior to his connection with the Canadian Electro Products Co., he had been general manager of the Baltimore Electric Alloys Co., in the manufacture of ferro-silicon and other electric furnace alloys, and for 13 years with the Aluminum Co. of America in various capacities, including design, construction and operation of a number of its plants. Mr. Falter was also general manager of the Shawinigan Electro Metals Co., Montreal, manufacturers of metallic magnesium, and he has also had considerable experience on hydro electric power plant work at Sault Ste. Marie and Shawinigan Falls, Canada.

The W. A. Jones Foundry and Machine Co., Chicago, Ill., announce that C. F. Ford, who for the past several years has been with the Chicago Pulley and Shafting Co. has joined its engineering sales forces. In the near future Mr. Ford will be located in Minneapolis as manager of the Jones branch there. Several years ago when the Jones Co. were in their old plant at North Avenue and Noble Street, Mr. Ford was their transmission engineer and acted in that capacity over an extended period.

New Companies

THE TITAN CEMENT CO., Ackerman, W. Va., has been incorporated with a capital of $500,000, to construct and operate a cement mill in this secteion. The incorporators are W. L. Sperry, J. W. Cook and D. R. Bartz, all of Ackerman.

THE MANUFACTURERS' KID CORP., New York, N. Y., care of the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia, Pa., representative, has been incorporated under Delaware laws with capital of $400,000, to manufacture leather. The incorporators are Harold J. Baldwin, New York; J. Albert Barton, Allentown, Pa.; and Franklin Haddock, Lynn, Mass.

THE RAYOLA CHEMICAL CO., Newark, N. J., has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts. The incorporators are James Hughes, Thomas A. Webb and John H. Valentine, 126 Commerce St., Newark.

GREEN BROTHERS, INC., East Providence, R. I., has been incorporated with a capital of $50,000, to manufacture paper products. The incorporators are Frederick M., George F. and Harry E. Green, all of Providence, R. I.

THE SHINGLE-GIBB LEATHER CO., Philadelphia, Pa., has been incorporated with a capital of $180,000, to manufacture leather products. Walton Gibb, 4650 Locust St., Philadelphia, is treasurer.

THE NOVELOID WORKS, INC., New York, N. Y., care of C. S. Lubin, 55 Liberty St., representative, has been incorporated with a capital of $10,000, to manufacture celluloid products. The incorporators are A. Storch, F. Klein and L. K. Wasser.

THE SUMMERS FERTILIZER CO., INC., 210 East Redwood St., Baltimore, Md., has been incorporated with a capital of $150,000, to manufacture fertilizer products. The incorporators are Willis R. Dresser, Walter P. Summers and James E. Totman.

THE TUSCUMBIA COTTON OIL CO., Tuscumbia, Ala., has been incorporated with a capital of $50,000, to manufacture cotton oil products. The incorporators are Leon Reed and N. A. Graham, Jr., Birmingham, Ala.; and W. H. Jasspon, Houston, Tex.

THE EBECO CHEMICAL CO., Newark, N. J., has been incorporated with a capital of $125,000, to manufacture chemicals and chemical byproducts. The incorporators are Charles Yorhum and Joseph Ebert, 13 Margaretta St., Newark.

THE BERTDICK OIL & REFINING CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $1,350,000, to manufacture refined petroleum products.

THE FREEMAN-HAMPTON OIL CORP., Wichita Falls, Tex., has been incorporated with a capital of $112,000, to manufacture refined petroleum products. The incorporators are J. H. Freeman, J. W. Hampton and Nathaniel Henderson, all of Wichita Falls.

THE SUPERIOR STEEL PRODUCTS, INC., Detroit, Mich., has been incorporated with a capital of $30,000, to manufacture steel products. The incorporators are Harry D. McCullough, Frederick J. B. Sevald and James A. Dompier, 9367 Navarre Ave., Detroit.

THE HENRY A. DEWEY CO., New York, N. Y., care of Moffatt & Devlin, 342 Madison Ave., representative, has been incorporated with a capital of $20,000, to manufacture chemicals, paints, etc. The incorporators are H. L. Dewey, S. M. Moffatt and E. I. Devlin, Jr.

THE BURKHART-SCHIER CHEMICAL CO., Chattanooga, Tenn., has been incorporated with a capital of $60,000, to manufacture chemicals and chemical byproducts. The incorporators are A. C. Burkhart, M. E. Lane and John H. Cantrell, all of Chattanooga.

THE WEBBER-WOOD SPAR MINING CO., 911 Third St., Eldorado, Ill., has been incorporated with a capital of $50,000, to operate feldspar properties and mills. The incorporators are C. E. Webber, D. L. Wood and A. H. Kinsall.

H. C. ZEAMER, INC., Pleasantville, Pa., care of the Capital Trust Co. of Delaware, Dover, Del., representative, has been incorporated under Delaware laws with capital of $500,000, to manufacture chemicals and affiliated products. The incorporators are H. C. and M. M. Zeamer, Pleasantville; and John E. Engle, Harrisburg, Pa.

THE FLINT STEEL CO., Davison Rd., Flint, Mich., has been incorporated with a capital of $75,000, to manufacture steel products. The incorporators are Edward H. Richmond S. and William L. Perkins, 1632 Garland St., Flint.

THE GRAY BROTHERS OIL CORP., Oklahoma City, Okla., has been incorporated with a capital of $50,000, to manufacture petroleum products. The incorporators are R. R. and C. C. Gray, both of Oklahoma City.

THE MELVILLE FERTILIZER CO., Tampa, Fla., has been incorporated with a capital of $100,000, to manufacture commercial fertilizers. Herbert M. Benker is president; Clarence W. Nelson, vice-president; and Fremont C. Stevens, secretary, all of Tampa.

THE T. H. E. HANOVER CHEMICAL CO., Hanover, Ind., has been incorporated with a capital of $6,000, to manufacture chemicals and chemical byproducts. The incorporators are James O. Taff, Charles A. Hunt and Earl Eldridge, all of Hanover.

THE LITTLE WONDER PRODUCTS CO., Burgettstown, Pa., care of the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia, Pa., has been incorporated under Delaware laws, with a capital of $500,000, to manufacture washing compounds and kindred products. The incorporators are K. D. and John J. Downey and H. A. McLain, all of Burgettstown.

THE STATES OIL CO., Room 815, 118 North LaSalle St., Chicago, Ill., has been incorporated with a capital of 50 shares of stock, no par value, to manufacture refined oil products. The incorporators are G. A. Buresh and Louis I. Gottlieb.

THE MELCHERS FULLERS EARTH CORP., San Antonio, Tex., has been incorporated with a capital of $100,000, to operate mining and refining plants for the production of fullers earth and affiliated products. The incorporators are L. L. Shropshire, F. J. Dykstra and E. G. Potter, all of San Antonio.

THE CAPE FEAR FERTILIZER CO., Fayetteville, N. C., has been incorporated with a capital of $150,000, to manufacture fertilizer products. The incorporators are R. E. Nimocks, A. L. McCaskill and A. H. Slocumb, all of Fayetteville.

THE WILSON OIL CORP., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., representative, has been incorporated with a capital of $250,000, under Delaware laws, to manufacture petroleum products.

THE BRUMUND BROTHERS-HUFKER FOUNDRY, INC., 4406 West Carroll Ave., Chicago, Ill., has been incorporated with a capital of $5,000, to manufacture steel, iron and other metal castings. The incorporators are Henry O. and Elmer G. Brumund and John Hufker.

THE SUNSHINE SOAP CO., Shreveport, La., has been incorporated with a capital of $100,000, to manufacture soap products. W. A. Vickers is president; R. L. Mayfield, vice-president; and J. M. Crimmett, secretary, all of Shreveport.

THE BRIGHTON ELECTRIC STEEL CASTING CO., Beaver Falls, Pa., has been incorporated with a capital of $25,000, to manufacture steel and other metal castings. Earl D. Townsend, Beaver Falls, is treasurer.

THE DUNDEE FERTILIZER CO., Winter Haven, Fla., has been incorporated with a capital of $25,000, to manufacture fertilizer products. W. T. Overstreet is president; and Bradford D. Williams, secretary, both of Winter Haven.

THE GULF SUPERIOR PETROLEUM CORP., Chicago, Ill., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $3,000,000, to manufacture refined petroleum products. The incorporators are George J. Woods, M. S. Gregory and H. Wunderlin, Chicago.

THE NIAGARA FALLS SMELTING & REFINING CO., Niagara Falls, N. Y., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws, to manufacture refined metals. The incorporators are Thomas J. Beardmore and Arthur Murphy, Paterson, N. J.

THE ROTHERT PROCESS STEEL CO., 622 Othello St., Seattle, Wash., has been incorporated with a capital of $1,000,000, to manufacture steel products.

THE WELLINGTON PETROLEUM CORP., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., representative, has been incorporated under Delaware laws with capital of $1,000,000, to manufacture petroleum products.

THE ALLIED CHEMICAL CO., Dallas, Tex., has been incorporated with a capital of $60,000, to manufacture chemicals and chemical byproducts. The incorporators are K. C. Scott, W. B. Sparkman and A. B. Farrington, all of Dallas.

THE GRAHAM CLAY PRODUCTS CO., Conneaut, O., has been chartered under state laws to manufacture brick and other burned clay specialties. The incorporators are Charles Follett and John W. Eckelberry, both of Conneaut.

Manufacturers' Catalogs

THE MCALEAR MFG. CO., 1901-7 S. Weste Ave., Chicago, Ill., has ready for distrib tion a new 128-page catalog, known as N 27, which illustrates many new devices, i cluding an individual temperature cont valve, specialties for all power plan vacuum and vapor heating system, oil fining and waterworks plants, plumbi systems and marine service, together wi illustrations showing their application a use. The individual temperature cont valve is self-contained and can be appli to any radiator, old or new, without ad tional piping other than the supply and turn. When the thermostatic member is for the desired room temperature, it au matically controls the opening and closi of the valve. The catalog contains a ve comprehensive detailed description of specialties.

THE UEHLING INSTRUMENT CO., Paters N. J., has issued Bulletin 113, on "Prep ing Flue Gas for Analysis."

THE YALE & TOWNE MFG. CO., Stamfo Conn., has issued a revised price list trolleys, cranes, switches, etc., which illustrated and described in Yale Cata 20D.

COOPER-HEWITT ELECTRIC CO., Hobok N. J., is distributing Bulletin 104, by L. Buttolph, on "Lab-Arc," a monochroma light.

E. J. CODD CO., Baltimore, Md., in a n bulletin describes chain screen doors furnaces and ovens, which have found plication in metallurgical, glass, chemi and boiler furnaces. The screen consists a multitude of individual strands of st chain, forming a penetrable transpar sheet of chain, which does not interf with the view of the interior of the f nace, the passage of the charge, or the to necessary for manipulation of the same.

THE NORTHERN ENGINEERING WOR Detroit, Mich., announces the publication a condensed catalog showing a few sta ardized designs of electric hoists.

THE TRUSCON LABORATORIES, Detr Mich., calls attention to a very attract "Architects Specification Handbook" wh has just come off the press. This book 108 pages, approximately 8½x11 in. binding is loose leaf, making the set specifications adaptable for use either a reference book for the A.I.A. filing syst or for any other classification adopted the architect's or engineer's office. It c tains complete specifications on waterpr ings, damp-proofings and technical coati

Coming Meetings and Events

ALPHA CHI SIGMA dinner, during Chemical Exposition, will be held Thurs Sept. 14, at 6:30 p.m. at Keen's Chop Ho 107 West 44th St., New York City.

AMERICAN CERAMIC SOCIETY will hol summer excursion meeting to Roches Montreal, Ottawa, Kingston, Toronto, H ilton, Niagara Falls and Buffalo, Aug. 13

AMERICAN CHEMICAL SOCIETY will h its fall meeting in Pittsburgh, Pa., Sep to 9.

AMERICAN ELECTROCHEMICAL SOCIETY hold its fall meeting in Montreal, Sept. 22 and 23. Headquarters will be at Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold annual convention and exhibition at At tic City, Oct. 23 to 28.

AMERICAN INSTITUTE OF MINING METALLURGICAL ENGINEERS will hold 126th meeting at San Francisco, Calif., 25-29, 1922.

AMERICAN SOCIETY FOR STEEL TREA will hold its International Steel Exposi and Convention in the General Mot Bldg., Detroit, Mich., Oct. 2 to 7.

NATIONAL EXPOSITION OF CHEMICAL DUSTRIES (EIGHTH) will be held in York Sept. 11-16.

NATIONAL EXPOSITION OF POWER MECHANICAL ENGINEERING will be hel the Grand Central Palace Dec. 7-13, the exception of the intervening Sunda

NATIONAL SAFETY COUNCIL will hol Eleventh Annual Safety Congress in troit, Aug. 28 to Sept. 1.

NEW JERSEY CHEMICAL SOCIETY has continued meetings for the summer, will resume them in October.

THE SOCIETY OF INDUSTRIAL ENGI will hold its next national convention exhibitions of labor-saving equipme the Hotel McAlpin, New York, Oct. 1 and 20.

he Tariff on Its Last Lap in the Senate

USPENSE regarding the Senate's action on the) tariff will be ended on August 19, when, according an agreement reached last week, the final vote will taken. There will be a certain sense of relief on e part of the interested public when the vote is finally nounced, even though the provisions of the bill cannot ssibly satisfy everyone concerned. As the Senate s proceeded with the consideration of the bill and s successively taken its action on dye embargo, tash, wool and sugar, apparently without rhyme, rean or any attempt at consistency, the average citizen s grown dizzy in an effort to follow all the gyrations d forecast the final outcome.

As far as the chemical industries are concerned, the cture is not entirely devoid of relief from the deep ue in which some have painted it. It is true that e dye embargo has now been eliminated by both the ouse and Senate and that the only hope for its furer consideration is to have the Senate replace it in e bill on final vote next Saturday. If this is not complished, the feature is lost, because the conferees ll have no power to consider it again.

On the other hand, little fault can be found with e ad valorem and specific rates to be levied on coal-tar emicals. This is particularly true when we consider at the Senate has applied the principle of American luation to dyes and chemicals covered in sections 25 d 26 of the chemical schedule, with a further reinrcement in the form of the flexible tariff provision of e bill which gives the President the power to alter tes as much as 50 per cent in order to rectify inequales in cost of production abroad and at home. Of urse we would rather have the embargo, and we still pe that it will prevail; but if it does not, the dye dustry will have obtained a large measure of otection.

The outlook for potash is not so favorable. The nate fairly ran amuck in considering this item, not ly eliminating from the bill the proposed sliding scale duties, but also declining to consider a bounty on oduction. In other words, potash was thrown out of e Senate, bag and baggage. And unless it receives me consideration on final vote the matter will have to fought out in conference committee, for the House l contains provision for a sliding tariff.

As intimated above, the Senate has just taken action two important matters, both of which will favor the emical industry. These are the application of Amerin valuation to imports of coal-tar dyes and chemicals d the so-called flexible tariff provision that gives the esident the power to raise or lower the rates as much 50 per cent. In adopting both of these provisions e Senate made radical changes in the original proposals. American valuation was first applied to all commodities, but under an attack led by Senator LENROOT, the proposal was amended so as to apply only to coal-tar dyes and chemicals. The provision for flexibility in the rates was strongly opposed by those who object to vesting in the Executive the tax-levying power of the Congress. Nevertheless the President's own preference for flexibility in the tariff undoubtedly had some influence in the Senate's adoption of the measure. According to its provisions the Tariff Commission will aid the President in determining the difference in cost of production of commodities abroad and at home. The President cannot change a specific duty to an ad valorem duty, or vice versa, nor can he transfer articles from the dutiable and free lists. An important amendment to the original measure was one providing for public hearings by the Tariff Commission. In ascertaining the difference in the cost of production the President is directed to take into consideration the advantages granted to foreign nationals by their governments.

Considering the belligerent attitude of some of the Senators and the fact that the Senate has already greatly modified the House bill, it is practically impossible to forecast the final action on any of these provisions. These will be determined only by agreement among the conferees of the House and Senate.

The Bedrock of Facts and Figures

IN PLEDGING their whole-hearted support to the work of the new Chemical Division seventy-seven of our organic chemical manufacturers have added their approval to the constructive service which the Department of Commerce is rendering to industry. As more funds become available Secretary HOOVER'S plans are gradually taking effect and it is increasingly evident that the department under his direction will reach and serve practically every branch of business.

It is peculiarly significant that the chemical manufacturers' first demand on the division is for statistics. Apparently even the monthly figures for the imports and exports of dyes have already proved their value to these practical business men. It is well known that a part of the dye industry must look to the world markets for the disposition of surplus production that is inevitable with efficient operation. Likewise other factors in the industry must keep closest tab on incoming goods, for their market may be swept away by a tide of imports. These industries want the actual facts and figures on which to base the control of their individual businesses.

But accurate information on production, consumption and stocks is even more vital—both to industry and to the country at large. The primary cause of runaway markets during a period of inflation is usually the lack

of just such data. Distribution is carried on unintelligently. Stocks pile up in one place and shortage exists in another. With the latter comes a false demand which in turn results in overproduction, market demoralization and loss.

The new Chemical Division, if given support, can become a valuable distributor of the essential business statistics of the industry. Furthermore, our trade associations—those representing the manufacturing chemists, the synthetic organic chemical manufacturers and the chemical equipment producers—are ideal agencies for carrying on this work, and they will be ably assisted by the government and by such national organizations as the Chamber of Commerce of the United States. What is most needed is the support of the individual business man, who must be made to realize the necessity for furnishing his quota of the needed data. Industry will not be guided intelligently until he is willing to take the guess out of his own business and get down to the bedrock of facts and figures.

Armchair Chemistry And Its Value

RECENTLY there was abstracted in *Chemical Abstracts* a paper entitled "Odor Value Analysis." In it a theory was advanced that odor is the response of the olfactory nerves to intermolecular vibration. It was further advanced that each pure substance has its own rate of vibration, which may, however, be too high or too low to be detected, just as there is in vision an ultra-violet and an infra-red region. It was further pointed out that most substances having any perceptible odor are unsaturated in the chemical sense. In addition, the authors have stated that odor undoubtedly could be modified by the addition of substances which do not of themselves have a very characteristic odor. Many substances become almost odorless as they approach purity, and yet when the impurity is isolated, it itself has almost no odor. The final suggestion is that since this theory would indicate that perfumers are wasting large quantities of material simply by nullification, constructive research would consist of the design of the most delicate kind of instrument and the most careful scientific work.

This paper interested us a great deal. The suggestion is interesting in itself and the theory might prove to be workable and the result far reaching. It is the kind of paper that often makes technicians and research men scornful, saying that it is an armchair paper representing no laboratory work of any kind and proving nothing. We can sympathize with that attitude, for we always seem to sense a trace of superiority in such articles, an attitude which might be translated to mean, "Let other people do the manual labor, we have done the thinking." Yet with all the objections, such papers have a vital place in research. Too often the research man is wrapped up in the details of manipulation. With his nose too close to the grindstone, he fails to get his problems in proper perspective. He often misses some valuable leads.

This same criticism can be applied with tremendous force to industrial research. The "vital" problems of industrial research are too often problems involving merely technique. How valuable it would be for industry if there were some men who could sit back and suggest things which "can't be done."

For Him Who Runs

SOMETIMES we wonder whether readers of th magazine know of and appreciate the excellent wo that is being done on behalf of business by the Fabr cated Production Department of the Chamber of Cor merce of the United States. An able series of bulleti and pamphlets has been prepared, the last of whi came to our notice some months ago. It is entitl "Perpetual Inventory or Stores Control." In our opini there is not a manufacturing executive today who c afford to neglect the subject matter of this pamphl Doubtless the same information can be obtained fr other sources, for there are books and articles on t subject and experts ready to give advice. But t service which the Chamber of Commerce is performi in this connection, making available expert knowled on many phases of business, deserves the approbation those in whose interest the work is done.

Another report recently received from this organiz tion announces that uniform cost accounting has be adopted in approximately 120 lines of commodities. mentions the benefits which accrue from a unifo system. First of all it inspires confidence that selli prices are determined on a fair basis and thus mak possible more intelligent competition. Obviously if co are figured in a haphazard manner one man may be serious detriment to an industry by selling at a pr which he thinks would return a fair profit but whi actually entails loss. Finally uniform cost-accounti systems reveal at once the unprofitable commodities any manufacturing enterprise.

We have mentioned but two of the topics on whi the Chamber of Commerce has rendered signal serv to business. Executives who will take the trouble keep in close touch with this organization will find th time and effort amply rewarded.

Sawing Off the Branch On Which They Sit

QUITE recently the fact that engineers and techni men are intermediaries between labor and capi has been given much greater recognition. Upon th capital must depend for the efficient carrying out processes. It must count on their loyalty and enthusia to make possible that extra percentage of yield u which the success of the whole enterprise may depe This enthusiasm is no abstract thing; it is transla into everyday work. For example: A somewhat dish eled foreigner sticks his head inside the little of of the plant foreman or the chemist in charge. "A pomp he leak," he grunts. "All right, JOHN," repl the chemist. If the technical man is loyal, eager, enth siastic, he will go at once and repair the pump or that it is repaired. If for any reason enthusiasm s lacking, he will sit around a while before he mo Those minutes spell money!

Hence the enthusiasm of the technical man is most valuable asset of chemical corporations. To o anything to diminish this enthusiasm would seem, the face of it, blind and absurd. And yet in the p few years how many companies are there who have cut the salaries of technical men, often out of proport to the reductions made in other salaries and wages? T twenty or thirty per cent cut from the payroll of company seems like money well saved to the board

irectors or the executive who is pinched in his yearly udget. But is it? If these executives and boards of irectors had only had close contact with plants, they ould realize that the money saved on the books shows p as money lost through little items none of which is vident in the cost accounts. How enthusiastically will technical man throw himself into his work if his ervices have just been re-estimated at 80 per cent of heir former value? It is a problem in elementary uman nature, and one that can be solved if the execuives will only put on a pair of overalls and stay around ny chemical plant for a few days.

At the same time that the salary cuts were being nade, it is likely that the company was calling upon the oyalty of its employees. How little such companies nderstand elementary psychology! Loyalty can never e given when the aim of the corporation and the aspiraions of the individual do not coincide. Upon that rinciple hangs all the law and the "profit."

A "Bucket Shop" In Chemical Industry

IT LOOKS as though we have been unwittingly guilty of aiding and abetting the operations of a company hat has the earmarks of a wildcat in the chemical inlustry. Last winter we printed in our Searchlight Section an advertisement announcing positions in the ngineering, chemical, traffic and sales departments of company purporting to manufacture metallic aluminum and aluminum compounds. A 3-year minimum conract at a good salary with annual increases was offered o successful applicants. It was stipulated, however, hat they must take a financial interest in the company, which would be "solidly protected." "These are not jobs,' but positions with real future ahead." With housands of chemists unemployed, it is small wonder hat there was generous response to the advertisement.

It appears now, however, that the glitter was not gold ut basest dross. A correspondent recently told us that e left a good position to become factory superintendent or this outfit and that while he was there he produced tons of alum, which was "the only salable material which the company ever made." He found a rather esperate situation, with workmen unpaid and dissatisied, and he dug into his own pocket to assist their amilies. He personally received only part of his salary nd when he left the company it owed him several undred dollars on personal account and for money adanced to the workmen. Subsequently he saw the glitterng advertisement which was published in *Chem. & Met.* nd other technical journals and straightway protested t the main office of the company, accusing the officials of ad faith. He was urged not to "spill the beans." The fficials took him into their confidence and showed the ctual situation. Among other things there was a stack f replies to the advertisement from men offering to invest" anywhere from $500 to $30,000 for a good job. Our correspondent's protest against this method of oing business having failed, he promptly resigned.

Since then several men are reported to have "invested" n the company after leaving good jobs, and the comany has meanwhile been ousted from its manufacturing lant. Other correspondents tell of having applied for ositions and of growing wary when they learned that hey might be tied to a lot of incompetent men who had invested" in the company and could not be discharged.

Whenever an incident of this kind occurs we feel that an apology is due to our readers, because they are entitled to protection against the operations of wildcat and fake concerns. Needless to say, this advertisement slipped into our columns despite a standing regulation that should have prevented it. The lines have been tightened still further, however, and we believe that our readers will be safe from future exploitation by irresponsible advertisers. The reader is entitled to feel that he can place the same confidence in an advertisement that he does in the text of a technical magazine, and it is the publisher's duty to throw every possible safeguard around him and merit his confidence. In return the reader should give prompt notification of cases such as the one here cited so that immediate exposure can be made and further dupes prevented from investing in a chemical bucket shop.

New Ideas For Old Industries

SEVERAL weeks ago we published an article describing a revolution in the production methods of porcelain manufacture—a revolution that was wrought by men having no prior acquaintance with the industry. Long trained and thoroughly skilled in the production methods of other industries, they brought to the porcelain field a new viewpoint. They studied this field in the light of their previous experience, and by judiciously combining what they had learned elsewhere with the fundamental necessities in porcelain manufacture they accomplished truly remarkable results in increased production and lowered costs.

This also brings to mind an experience some years ago of a brewer acquaintance of ours. In the course of his business dealings he acquired the burden of ownership of a bankrupt motorcar plant. As this property stood when our friend acquired it, it was much more of a liability than an asset. Our friend made beer, and at that time hoped to continue to do so; and so he viewed his new property as something to get rid of as soon as he advantageously could. After some study, he determined that the fault was with the motorcar plant management and not with the product. So he carefully reorganized this management, using what he knew of brewing business methods as a basis and disregarding the mushroom-grown methods then prevalent in the automotive industry.

The results obtained were highly satisfactory, to say the least. In 3 years time he had established a steady market for his car, the plant was running profitably, and he was able to sell the property for a splendid sum. The impetus of his reforms holds to this day and the present owners have cut many coupons as a result of business ideas brought into their plant from a totally foreign industry.

It is with a knowledge of the possibilities of the outside viewpoint in mind, a knowledge based on many examples other than those cited above, that we are often filled with wonder at the attitude of so many plant owners and executives. They are so often hesitant to employ an engineer unless he has had years of experience in their own industry. And they angrily tell the consultant that he cannot hope to show them anything of value about a game of which he knows nothing and they know almost everything. Surely, if we will but delve a bit into our memories, we can all find examples at least as pointed as those given here of the surprising growth of the seed of a new idea when planted in the fertile soil of an old industry.

Castings of Electric Iron

To the Editor of Chemical & Metallurgical Engineering

SIR:—Mr. Elliott, in his excellent paper read before the last meeting of the Electrochemical Society on "Cast Iron as Produced in the Electric Furnace, and Some of Its Problems" and republished in your magazine of July 19, thoroughly covers the subject from the standpoint of practice and utility. While the conditions as enumerated are those of Cincinnati or such other center near by blast furnaces, they do not hold on the Pacific Coast. To operate a cupola our problem is the obtaining of pig iron of quality and sufficient cheapness together with cheap cast-iron scrap. Freight on Eastern iron amounts to $14 to $19 per ton, depending on whether shipped by rail or water. Foreign irons can be laid down on the dock at about $30, but of questionable quality in the majority of cases. Cast scrap is now selling at about $23 per ton, and steel scrap for general melting at $14. As against these you have steel borings selling at $6 and cast iron borings selling at $7. With a conversion cost of $12 to $15 per ton in the electric furnace working on cheap scrap, you can readily see where cold melting is more economical than the refining of hot metal from a cupola.

When the Los Angeles Foundry Co. first started manufacturing electric furnace cast iron an acid bottom furnace was used, but this was quickly changed to basic, when it was found that we could not make a quality casting in the acid furnace. We have tried both duplexing and cold melting and prefer cold melt iron to duplex iron for several reasons:

1. It can be made from steel scrap with a low phosphorus content, giving a much stronger iron.

2. It can be melted down under strong reducing atmosphere with a carbide slag. This means that the period of refining is lengthened from ½ hour to about 3 hours. What is more important, the slag protects the metal during the period of fusing and melting, and before there has been any chance for the metal to dissolve oxides or gases which later cannot be removed.

3. Metal is never exposed to chance oxidation, as happens in the cupola when not properly running. It is a well-known fact that very often iron can be oxidized in the cupola, and even the most rigorous basic electric furnace refining will never bring that iron back into the quality class.

Electric iron is always more difficult to machine than cupola iron, and I thoroughly agree with Mr. Elliott that this is caused primarily by the elimination of microscopic gas pockets giving a much denser and sounder iron. Electric iron, however, can be so manufactured that it will have all of the excellent qualities of basic iron, and yet can be machined at high rates of speed. At the present time we are making gray iron castings of the analysis: carbon 3.25 to 3.75 per cent, silicon 2.00 to 2.50 per cent, manganese 0.30 to 0.50 per cent, sulphur less than 0.04 per cent, phosphorus less than 0.05 per cent which fills the conditions perfectly.

The above is a general statement of the conditions in the southern Pacific Coast region and especially under our conditions of operation, and while they are indicative of our experience, they may vary greatly in other sections of the country. The freight problem is a serious one out here, and from the general trend can see a great expansion in the manufacture of electric furnace iron in the future. With the wonderful development of the power companies there is the assurance of abundant electric energy to serve our future needs.

Chemists in Public Life

To the Editor of Chemical & Metallurgical Engineering

SIR:—I wish to thank you for sending me the July 5 issue of *Chemical & Metallurgical Engineering*, as was very much interested in your editorial review of the question of the public and semi-public activities of chemists. Personally I think you have put your finger upon the weakness of the chemical profession, if it may be so called. In my very humble opinion, the reason the public has failed to appreciate chemistry and chemists has been due to the fact that chemists, as a class, have failed to distinguish themselves in the communities in which they live from the large group of manual workers. The reason for their tendency to become recluses and for their lack of interest in public affairs has always been a source of wonderment to me. University professors, as a rule, are not so subject to this criticism since they are, by the very nature of their work forced into a larger participation in community affairs unless they are research men.

As to the reasons for this condition, it has seemed to me that our university and college courses in chemistry lack what may be called directional emphasis. As a result a chemistry student who has seen the emphasis placed on laboratory work associates this in his mind as the goal of chemical training. If our colleges and universities had a short course in what may be called "vocational guidance for chemistry students," in which could be pointed out the opportunities for executive, administrative or consulting work and in which the obligation or opportunity of the chemist to his community could also be indicated, I believe the situation would improve within a generation.

As you know, I am connected with a company which receives a great many applications for positions each year from graduates of our universities. In practically every case the applicant asks for laboratory work and ceases to be interested when informed that the only openings available are in the operating, sales or administrative departments. In other words, the opportunity to use his training for what may be called mental task does not seem to appeal as does the opportunity to use his hands in mere mechanical laboratory work. I always wonder if laboratory work as such does not have a certain "play" appeal and possibly gratifies the instinct possessed by us all to manipulate apparatus in order to enjoy the glow of satisfaction derived from the successful outcome of the experiment.

Chicago, Ill. S. L. REDMAN.

The Business Side of Chemical Manufacture

This Article, the Sixth of the Series, Presents the Purposes, the Limitations and the Great Advantages of Cost Accounting—The Methods Are Briefly Discussed and a Few of the Practical Difficulties Enumerated

By Charles Wadsworth, 3d

F A young doctor has as much money at the end of a year as he had at the beginning and has paid his expenses, he calls it a good year. That may sound ther rudimentary as accounting. It is. But it is not whit more rudimentary than most commercial cost ding until quite recent years.

Of course it must be remembered that there was not arly so imperative a need for accurate costs until thin the last 30 years. Previous to that time the world as a manufacturers' market. Demand was always in cess of production, or nearly always. Manufacturing iciency was not so perfect and it was nearly impossie to flood the market in a short time. Therefore the lling price of a commodity was a comfortable fraction ove manufacturing costs. Since the margin was not close, the less complex problems of markets and disibution permitted the manufacturer to read the pulse his business from a number of indicators which perience has taught him to respect, such as sales, sh balance, bills receivable, bills due and the general eling of health or the reverse.

Modern cost accounting is a much more reliable and much more flexible method of observing and controlg any business. It is becoming a prerequisite to inlligent executive action. The modern executive can-t possibly keep in touch with his business as the l-time business head could. Therefore accurate cost alysis is coming to be his business eye.

One Danger of Cost Accounting

There is one very great danger in this and it is the nger into which many large corporations have fallen. st analyses look much the same in one business as in other. So, frequently, a successful executive in one e of business sees a set of cost figures from another e of business and as they look perfectly intelligible, is confident that he understands them. He sees at the trouble is. He says so. Boards of directors lieve him. He is invited to take charge of such and ch a company. If this new company is a chemical nufacturing company and he has had no experience that industry, heaven help the company. Even execues who have grown up in chemical plants, but whose in contact is now through costs, often do absurd ings. In our last article on plant yield we mentioned almost universal example of lack of executive con-t with manufacturing conditions. The query as to y such and such a yield is low or such and such a t is high when the variation observed is within the ssible limits of accuracy illustrates the lack of execue contact and the danger of depending too much on sts.

The Aims of Cost Accounting

Cost accounting must be developed as a theoretical stem first and then some practical considerations cussed. Naturally, in an article such as this, telegraphic brevity and glaring omissions must be the rule, but we can perhaps give some conception of the advantages, the difficulties and the methods of cost accounting in chemical plants. Many manufacturers have objected, and many still do, that their business is unique and ordinary cost accounting could not be applied. They further object to the cost of installation and operation. Finally, when it's all in, what have you got? Can you tell him anything that he doesn't know? He's getting as much as the market will stand for all his products and he's making money!

The answer should be cautious and not sweeping. Cost accounting, Mr. Manufacturer, will tell you many things that you don't know. It will show you what factors go into the manufacturing cost and it will enable you to put your finger on the items that are costing too much. It will segregate the selling cost and indicate whether that is too high. It will enable you to determine which of your products is the best money maker. Perhaps some are actually losing money. It will show you the definite price limits of raw materials and labor. It is true that the system will cost something to install and something to operate. The forms cost money to print and take time to fill them out. The accounting department will have to be increased. But the expense will be small compared with the gain. We urge you to try it, but not until you and your whole organization understand and believe in cost accounting. Your men must realize that it is not a spy system and that it is to their interest to make the system accurate and dependable. Unless they are behind it the system will have relatively small value. (Many fail to appreciate the necessity of the co-operation of the men in this work.)

How Accurate Are Costs?

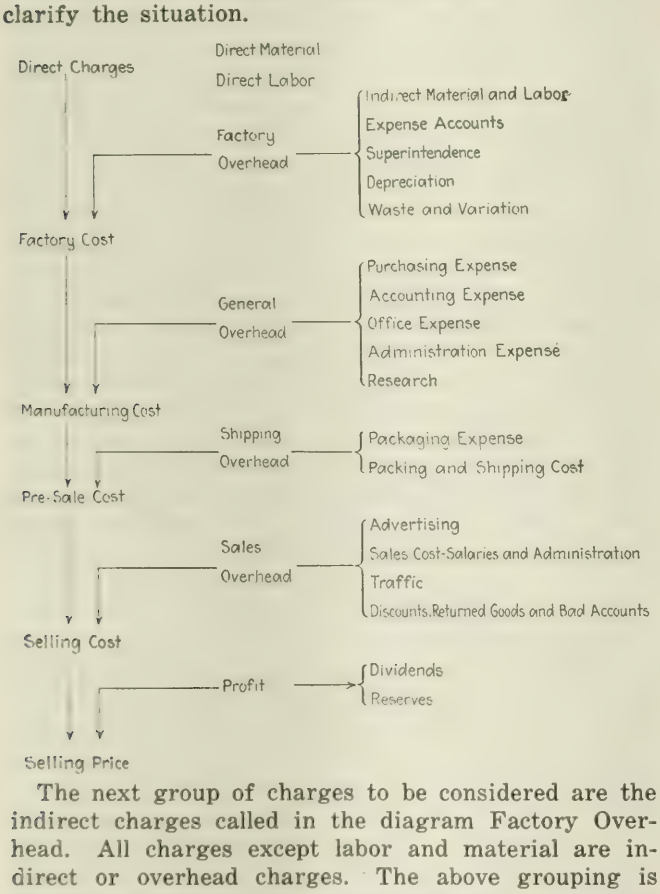
As we discuss the details of cost accounting it will be readily seen that the accuracy of the system will be directly proportional to its cost. The point of marginal utility must be determined. For example, it might be possible to estimate costs with an accuracy of 10 per cent under a given system. With a few more forms and an extra clerk or so the accuracy might well be increased plus or minus 2 per cent. Still further refinement would be possible at increased cost, but might be considered unnecessary. For example, assume that handling and trucking of material amounted to a considerable item. The total cost might be split equally among the products. However, an accurate distribution could be obtained only through a voucher and order system. This might make a difference in cost of some of the products amounting to several per cent, due to greater accuracy of distributing the charges. Is that greater accuracy worth while? It is a question which must be specific, but which should always be asked. Relatively few do ask the question, for the tendency is, if you have a cost system, to go the whole hog and install many wholly unnecessary forms.

All cost accounts are based on systematic arrangements of expenditures. Payments by the company are recorded in books of original entry, usually called journals to distinguish them from ledgers, which are the books of final entry. A typical journal account would be "payrolls," to which all money paid to employees would be debited each week. The account is then credited as the various amounts are charged out to the plants in which the employees worked. When the credits equal the debits the account is said to be balanced or "wiped out." Journal accounts are wiped out as frequently as possible.

Those items of cost which can be charged directly from the journal accounts to the departments as above are called Direct Charges. These are of two kinds—Direct Material and Direct Labor. The terms signify that the material and labor so itemized were definitely used in that process. That much of cost finding is simple, accurate, unquestionable—BUT

Indirect Charges—The Real Problem of Cost Accounting

Before we go further a simple diagram will help to clarify the situation.



The next group of charges to be considered are the indirect charges called in the diagram Factory Overhead. All charges except labor and material are indirect or overhead charges. The above grouping is somewhat arbitrary, but is a very frequent practice and can be commended because it is comprehensible. Indirect charges cannot be made directly from the books of original entry to the proper ledger account. The charges are first grouped under intermediate accounts with proper headings. For example, the journal payroll account is debited to process ledger accounts and, as far as repair and shop men go, to a shop account which is an intermediate account. From this account time is charged out on a basis of orders by different plants. Another type of indirect charge is an account such as superintendence which is split up not by an order system but on an arbitrary percentage basis. One general principle which should be followed in making indirect charges is that under no circumstances should an extraordinarily large charge be made in a given period to boost the cost of production unduly. If a large amount of repair work is undertaken in a given month or fortnight it would be decidedly unfair to charge all of that repair work to the cost of making the material produced in that short time. To avoid this a special account is opened called deferred charges to expense and this account is gradually wiped out by crediting monthly (or fortnightly) charges made to various ledger accounts. This is also the method for handling such charges as taxes and insurance where payments are made once or twice a year and the amount distributed to the various producers periodically.

If we now return to the diagram the various items deserve some more detailed consideration.

Indirect Labor and Material—For example, repairs are made on a piece of equipment. The wages of the shop men, machinists, carpenters, etc., are charged out of the Payroll Account into a shop account and the time consumed on that particular repair job is charged against the department in question. Similarly the material used on the repair has been debited to Stores and is now charged out to the department. Again, oilers and motor repair men who work in a number of departments are charged to a general account and the account divided appropriately. Material handling and trucking in the factory are also included in indirect labor.

Expense Accounts are more difficult still. Such items as steam, electric power, compressed air, rent, taxes, insurance can not be easily evaluated for a given product. The total cost of such items for the whole plant must be obtained by accumulating all the charges in accounts with proper headings. Then these charges must be distributed according to the amount of steam or air or power consumed or, in case of rent or insurance, according to the value of that part of the property used by each department. Obviously this involves either measurement or estimation of the quantities distributed in the first instance. This can be accomplished with more or less inaccuracy.

Superintendence is again an item the total cost of which must be divided. Shall the division be based upon the capital value of the individual plant, upon the total value of the product made, or upon an estimated proportion of time spent on each plant? In instances where the superintendence charges are high, the policy of distribution would make an appreciable difference. This brings us to a generalization which is extremely important. *Costs can be made to vary to an amazing extent depending on the policy of distributing overhead charges.*

This will become more and more apparent, and right there is the meat of the whole problem of cost accounting. It is the reason why standardization of costs is difficult. One manufacturer distributes his overhead charges according to the capital value of his respective units, another according to the value of the product made. One may include research as a capital charge to be written off. Another prefers to write it off as current expenses. All these variations make for variations in cost. In other words, it amounts to this: The distribution of indirect charges is a matter of business policy and this fact makes it impossible to say *this* is the right way to distribute your overhead charges

There can therefore be no absolute method or figure for osts no matter how accurately the system is devised. t is well to bear these facts in mind when you are dealng with costs. They are not heaven-sent mathematical ertainties, but they represent an intelligent approxiation and the most valuable instruments yet devised or determining business health.

Depreciation—the Greased Pig of Cost Accounting

A prime example of the effect of business policy upon osts is evident from the treatment of *Depreciation.* A good friend of mine remarked that a discussion of lepreciation resembled a debate on free will or deerminism. It reached no definite conclusion as to what vas ultimately correct. Depreciation represents the liminution in value which equipment or buildings ndergo with use and time. Some accountants believe hat depreciation should be figured at a definite per ent of the original value. A machine costing $5,000 f depreciated at 10 per cent per year would have values f $4,500, $4,000, $3,500, etc., at each succeeding year. nother theory would depreciate at a fixed per cent of hat year's value. ($5,000 at 10 per cent equals $4,500 t the end of 1 year; $4,500 at 10 per cent equals 4,050 at the end of 2 years, etc.) Others believe that epreciation should be modified to correspond with the eplacement value of the equipment. For example, at he end of 3 years the cost of the $5,000 machine is ctually $6,000. Ought not the amount written off e a definite percentage of $6,000 instead of $5,000?

Remember the theory behind depreciation is to set side out of profits a reserve for replacement of equipent. It has always seemed to me that the simplest ethod of figuring depreciation should be followed and ne percentage set high enough so that there is a defiite factor of safety in it. The same policy should be dopted in determining depreciation that is used in eciding about the installation of new types of equipent. In some industries—for example, cement—new quipment is installed if it can show a 20 per cent eturn on the investment. Therefore a conservative epreciation rate in that industry would be between 0 to 15 and a normal depreciation about 10 per cent.

Many industries and firms are foolishly demanding nd frequently miss extremely good investments on nat account. They will not invest in changes of equipent unless the return amounts to 100 per cent in a ear. Heavy chemical firms are notably conservative nvestors and their depreciation rates are usually high.

Another refinement in estimating depreciation consts of estimating the rate on each piece of equipment eparately or each major piece costing over a definite mount. Except as a method of arriving at the average epreciation in a given unit, this does not seem necesary or wise. What you are after really is an adequate eserve for replacement and an estimate of the capital alue of the plant on which interest must be earned. can be rather easily understood if a small company e considered, with investment of $50,000 in equipent. The value of that equipment will depreciate , say, 10 per cent a year. Then in 2 years it will be orth $40,000. Out of the profits a reserve for dereciation should have been set aside in that time of 10,000. Thus the total capital will be the same.

As a matter of fact this is not universally done. irms will spend a tremendous amount of time estiating depreciation rates with great care so that costs will be accurate and income taxes as low as possible, but no cash reserve is set aside for depreciation in any way. It is just a book figure and has only theoretical significance.

Still another factor of depreciation is commonly called *Obsolescence.* It refers to the decrease in value of a machine due to the development of better manufacturing processes. In some industries obsolescence is a much larger factor than depreciation, and in all businesses it must be considered.

There is yet another difficulty introduced into cost accounting by the necessity of meeting definite specifications. Some of the material may not come up to standard, in which case it may either have to be marketed at a loss, discarded completely or worked off in batches of standard material. The cost treatment obviously will vary with the method of disposing of the material. The treatment of waste, or spoilage as it is called, is most difficult when the material must be discarded. How shall the loss involved be treated? Shall it be accumulated in a special account and written off in small monthly increments, or charged off once a year in the profit and loss account? The former way is preferable.

General Overhead

Following the desirable doctrine of simplicity, a large majority of firms add all the charges for purchasing and stores, such as salaries, wages, etc., to one general account. This account is fairly regular and is wiped out each month (or period) by debiting it proportionally to the ledger accounts. There is a more complicated method which consists of wiping out the purchasing and stores accounts by adding a small fixed charge to everything that is purchased to cover the cost of purchasing. This requires more bookkeeping and is scarcely worth the effort.

An exactly similar procedure to that given in the first part of the last paragraph can be followed with the distribution of Accounting Department Expense, Office Expense and Administration Expense. Each of these items is fairly steady and thus the general overhead does not offer as much complication as the factory overhead. The amount varies very slightly from month to month and it is entirely safe to wipe out the account from month to month. No deferred charges need arise. The differentiation of the General Overhead from Factory Overhead is entirely logical. Even in firms which operate only one factory and therefore do not compare one factory cost with another, the practice is desirable. The types of accounts are quite different.

Cost of Packaging and Shipping

Just a word is needed on this point. The charges embraced in this heading are not strictly manufacturing charges and should therefore be segregated under a separate heading. This is exceedingly convenient, as the cost of this item is frequently higher than necessary. Much attention is devoted to production efficiency in the plant and often many hundreds of dollars are wasted by letting this item slide by.

In many industries there are very big problems involved in this work. Carboys, barrels, drums, etc., are returnable and represent a very large capital investment in themselves. Definite regulations in the crediting of these items must be followed and enough margin allowed to take care of repairs. Replacements should

take care of themselves. The whole container system should as nearly as possible be on a self-supporting basis. This is usually taken care of by a service charge included in the price of the commodity and credited to a special fund for taking care of these items.

Selling Overhead

Finally, after production expense is all accumulated, the cost of selling the product must be added. This means that the cost of advertising, the sales department expenses, including many items not usually thought about, such as warehousing expenses, freight to distributing points, trucking, etc., must be collected in appropriate accounts. There is opportunity for many complications in this work. Take this little problem. Sulphuric acid and alum are sold by one firm. Assume that sulphuric acid is placed largely on contract during October, whereas alum is sold largely on spot sales throughout the year. The volume of sales is the same as to cash value, but the alum is literally ten times as difficult and expensive to market. Is it fair to split the selling expense equally? In such a clear-cut case as the above it might be possible to make a fair distribution, but in practice such clear differentiation does not exist. Therefore distribution is usually carried out on the simpler basis of cash value of product.

Computing Selling Prices

With the addition of the selling overhead we have completed the compilation of the total cost of the product. To this must now be added whatever profit is to be made in order to determine the selling price. That sounds like putting the cart before the horse. Many executives and most salesmen would be inclined to laugh at "adding whatever profit is to be made." The idea is that the most you can get is the correct profit. However, the mechanism of calculating minimum prices and the extensive use of these in the chemical industry make the above statement pertinent. One of the main advantages of cost accounting is that it will tell you when a product is losing money and it is losing money when the total cost plus a fair return on the capital invested is greater than the selling price.

Interest on Borrowed Money

Up to the present time no mention has been made of interest on borrowed capital. Many cost accountants believe that it should be considered an expense and treated exactly as an expense account is treated. It is more logical, however, not to include it in the manufacturing cost. If the capital was not borrowed, but subscribed by the owner, there would be no such item in the cost. Therefore it should be taken out of profits and not added as an expense. This is a rather moot question and the confusion arises from the fact that interest on bonded debt or stock dividends must be paid and are therefore regarded as fixed expenses. Actually, however, they do not belong in manufacturing cost. The disposal of profits to proper reserves, etc., is not a problem of cost accounting but of business policy, and does not belong here.

Some Plant Problems in Cost Accounting

Cost of Raw Materials. It is easy enough to write down the cost of material when it is purchased from an outside source at a definite cost. But suppose you made a product in one department, consumed part of it in another department and sold the rest, how muc should department 2 pay for product made in depar ment 1? Shall it pay market price or manufacturi cost? There is no correct way of handling this pro lem. It is a matter of business policy solely. It wi make a decided difference in the profit made on eith product and executive decisions must in either ca take into consideration these variations.

Joint Products and Byproducts are also difficult handle, since any distribution of cost is arbitrary. T only fair way is to consider the profit on the group a whole. Take the example of muriatic (hydrochlori acid and saltcake (sodium sulphate). Both of the products are made in the same reaction. If an ar trary distribution of overhead is made, it is concei able that a greater profit might be found in muriat whereas on another basis a greater profit would accr from salt cake. It would be folly therefore to specia ize in the sale of one under the mistaken idea that mo money could thus be made. The above is precise what happened in another process in my own exper ence. Beware of squirrels!

Research is a difficult thing to handle from the a countant's standpoint. First, what is it? In additi to laboratory research, this item includes developme work, drafting work, design and engineering wor In other words, all things tending toward production material which do not represent real value. It is t "overhead" of plant construction cost. The distinct is not clean cut and is ultimately a matter of degr rather than kind.

For accounting purposes it can be divided into r search on products already manufactured and resear on new products. This division is somewhat depende also on the kind of industry. Dyestuffs and fine chem cals have the largest ratio of research per unit capit and it is usual for them to write off the research charg into current expenses by adding an amount equal to average of the past 3 months. This procedure is d sirable, as dye processes may have very irregular u and may not be able to bear their share of any amo ization of capital charges annually.

Postlude

Do you now resemble the sweet young lady who t the clergyman that he had made the subject of fr will prefectly intelligible? Do you understand c accounting perfectly? Well, neither does anyone el but as it is the greatest single aid to intelligent prod tion, it would not be a bad idea to study it.

This series of articles on the Business Side of Che cal Manufacturing ends with this article. This mea simply that the six articles originally planned ha been published. Other articles will appear from ti to time, and we have the promise of special articles these non-technical phases of chemical manufact from eminent specialists. The subject is too vital leave and it shall be one of the purposes of *Chemical Metallurgical Engineering* to awaken the technical m to the vital nature of non-technical work and the necessity of his mastering the technique of th departments if he is to attain to effective execut positions. At present he is too much dominated the business man whose mastery of business techni has made him more valuable to industry than the te nical man without it. This has been bad for indus as well as for the technical man.

A Visit to the Plant of the Nobel Industries, Ltd., at Ardeer, Scotland

By Ellwood Hendrick

AN INTERESTING feature of the Glasgow meeting of the Society of Chemical Industry was the visit to the Ardeer works of the Nobel Industries, Ltd. The party was restricted to 100 persons, who left Glasgow on a special train and arrived at the factory about 10 a.m. Here, after giving up all smoking materials, cigar lighters and matches, the visiting company was divided into several groups of about twenty, each group being placed in charge of one of the chemists of the establishment for an inspection of their various departments. The passage through the sulphuric acid and nitric acid plants was just rapid enough to be a bit tantalizing, but the whole tour gave a clear idea of the general arrangement of the works. At noon the company met in the great hall of the club building for lunch. Sir Hugh Anstruther, vice-chairman of the board, presided and Lord Cochrane of Caith, together with one or two other directors of the corporation, was present as well as many of the staff. A quality of measured and proper conviviality reigned which was unusual to those of us who are accustomed to lead from dryness rather than the bottle on festal occasions.

The chairman made a short address in which he declared that their research staff had been their key to progress. Business, he said, was dull; they were working only 5 days in the week; but they continued to promote research at all times with energy and fervor, as their best means of making advancement. Without it they could not have done their work during the war successfully, nor could they have continued to produce needed things up to the armistice. Dr. Armstrong, the new president of the Society, made a happy response, and then the company was off again to witness a series of demonstrations of the testing of blasting explosives and demonstrations of some of the properties and of several applications of explosives.

It was noted in a descriptive pamphlet given to each visitor that in some explosives, such as black powder, the burning of successive layers of the substance takes place at a velocity of only a few meters per second, whereas in the more modern blasting explosives the combustion travels through the mass at from 1,000 to over 8,000 meters per second. This rapid type of explosion is called detonation, and the impulse passing through the mass is called the detonating wave. A few

FIG. 1—VIEW OF ARDEER FACTORY OF NOBEL'S EXPLOSIVES, LTD., SHOWING ACID PLANTS

detonating explosives, such as mercury fulminate, flash almost immediately when ignited, whereas others explode only after burning for some time; or they may burn up entirely without detonating. The former more sensitive detonators are used to initiate the wave in the latter. Thus a metal tube containing the initiating explosive is imbedded in the mass of the other and then ignited by safety fuse or an electrically ignited composition, which detonates the main explosive.

Experimental Demonstrations

Three experiments showed the difference between an explosion caused by rapid burning and one due to rapid detonation. The demonstrations included an explosion of gunpowder by safety fuse alone; an explosion of dynamite by a detonator fired by a safety fuse; the explosion of dynamite by a detonator fired electrically. A second series showed 8 oz. of Cambrite No. 2 ignited by a flame and 8 oz. of Cambrite No. 2 detonated by a No. 6 detonator. The differences were very marked and the experiments most instructive. Demonstrations were also made of the testing of blasting explosives. The "power" of an explosive is a function of the actual pressure developed by the products of decomposition, which are chiefly gaseous at the time, and of the velocity at which the pressure is developed. To determine the former, the lead block test is made.

The apparatus for this test is a lead cylinder containing a cylindrical cavity into which a given weight of the explosive to be tested is placed, tamped with dry sand, and fired. The cavity so produced is measured by pouring water into it from a measuring cylinder and comparing it with the amount needed to fill the bore before the explosion. This determines the shattering effect.

The ballistic mortar test determines the gas pressure developed or the heaving effect. In this test, the explosive is contained in a horizontal cavity in a steel block or mortar which forms the bob of a huge pendulum. The shot is tamped by means of another steel block which forms a sliding fit into the first. When the shot is fired the tamping block is propelled into a sand bed beyond it and the pendulum is swung back in the opposite direction. A marker shows how far, on a circular scale, the pendulum has swung.

Velocity of Detonation

The velocity detonation test is an important factor in testing the quality of an explosive and the method is very ingenious. A quick explosion is suitable where the size of the fragments is of no importance, but if too great pulverizing action is to be avoided, as in quarrying or getting out coal, then an explosive of comparatively slow detonation is desired.

The apparatus consists of a thin lead tube containing a core of TNT. This is called "TNT fuse," because the detonation wave travels through TNT at a very uniform rate. If a length of this tube is detonated simultaneously at each end, the detonation wave will meet at exactly the middle point of the fuse, and this point may be readily found by laying the fuse on a lead bar; then the point at which the detonation waves meet is clearly shown by the presence of a fine line across the lead bar, perpendicular to the fuse. But if the ends of the fuse are detonated successively by a detonation wave which travels along a cartridge of known length of an explosive to be tested, then a certain time will elapse between the detonations at the respective ends of the TNT

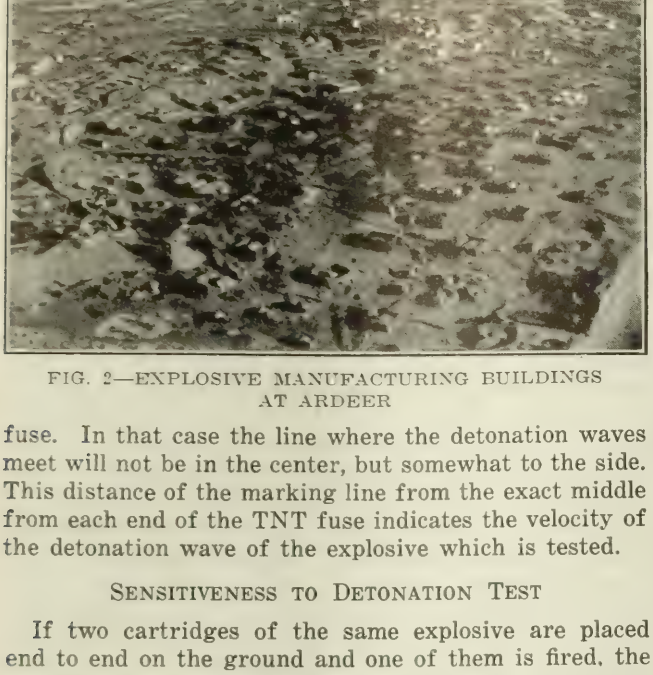


FIG. 2—EXPLOSIVE MANUFACTURING BUILDINGS AT ARDEER

fuse. In that case the line where the detonation waves meet will not be in the center, but somewhat to the side. This distance of the marking line from the exact middle from each end of the TNT fuse indicates the velocity of the detonation wave of the explosive which is tested.

Sensitiveness to Detonation Test

If two cartridges of the same explosive are placed end to end on the ground and one of them is fired, the detonation of the first is transmitted to the other. If the experiment is repeated, gradually increasing the distance between the cartridges, it will be found that the range of transmission is not the same for all explosives. The maximum distance at which one cartridge can propagate explosion in another is known as the Ardeer double cartridge test or the "A.D.C." Cartridges were shown which failed to "catch" an explosion this way at 4 in. distance from the same kind of cartridges which were detonated, whereas another flared up when placed as far as 24 in. distant from a similar cartridge that was shot.

Safety Explosives Gallery Test

This determines how far it is possible to go, or rather how much of a "safety" explosive may be fired in a mine in the presence of fire damp or coal dust. The company's "gallery" is a long steel chamber like a long boiler, into which a mixture of coal gas is introduced and openings in the gallery are sealed with paper. Coal gas is introduced so as to produce an explosive mixture with air. Then varying amounts of the explosives to be tested are shot into the container. When an explosion ensues, it is known that the limits of safety for that powder have been reached. Similar tests are made with coal dust and air mixtures.

The final series consisted of demonstrations of some properties and practical applications of explosives. Three dynamite cartridges were fired successively, the first in the open air, the second partly confined, and the third tamped on an iron plate. The third experiment showed a method in use for cutting steel plates in the destruction of old ships. To show the use of explosives in the removal of obstacles, a wooden palisade was set up and a row of cartridges laid close to the foot and confined by banks of the earth. To dig a trench for drainage purposes a row of holes was bored in the ground along the line of the proposed trench and a cartridge placed in each hole and exploded. A large cast-iron cylinder, which was the top section of a nitric acid pot condemned to the scrap heap, was broken into two pieces by the application of a plaster charge to the inner face of that portion of the ring which was next the ground.

A large cast-iron pot was also consigned to the scrap heap, but owing to its size and shape, a plaster shot would have been dangerous on account of the flying pieces of metal. In this demonstration the pot was filled with water and the explosive suspended in the center and fired. The water acted as a transmission medium, causing a heaving pressure against the sides of the pot, breaking it up into small pieces very effectively and within a comparatively small area. Then followed demonstrations of distress and sound signals designed for ships at sea, and finally a chimney stack was demolished and caused to fall in a definite direction by removing bricks from the base of the stack, leaving only supporting pillars on the side on which it was required to fall. The pillars were then bored and charged with the required weight of explosive.

An extensive exhibition was provided in the club building of materials made by the corporation at its various plants which, besides explosives and the heavy chemicals to make them, included gas mantles, celluloid materials, nitrocellulose cements and varnishes, plastic wood, metal goods, bicycles, soaps and other materials.

Heat-Treating Steel Castings to Spheroidize Cementite

By using proper magnification, it is usually possible to resolve the eutectoid areas of well-annealed carbon steels into lamellar pearlite. It has ordinarily been supposed that an extremely long anneal just below Ac is necessary to spheroidize the structure—i.e., cause the cementite plates in the pearlite to break and ball up into small spheres, through the influence of surface tension.

H. C. Ilsen points out, in July *Forging and Heat Treating*, that a steel having spheroidized cementite is analogous to a good bearing metal, in that it contains small hard particles which resist wear imbedded in a relatively soft, tough matrix. He tested some open-hearth cast steel (C 1.0 per cent, Mn 0.71, P 0.045 S 0.042 and Si 0.37) which after annealing 2 hours at 1,400 deg. F. showed a pearlite structure, coarse fracture and the following physical properties: tensile strength 103,100 lb. per sq.in., yield point 56,640 lb per sq.in., elongation 6 per cent in 2 in., reduction in area 6.3 per cent, and Brinell hardness 233. $Ac_{1,2,3}$ for this steel was at 1,325 deg. F., and Ac_{cm} 1,485.

Results of several heat-treatments are given, from which it appears that after correct preliminary heat treatment, this steel can be spheroidized by a 1-hour draw at 1,300 deg. F. Best results were had by a rather complex heat-treatment: Anneal 2 hours at 1,400 deg F., to equalize the phosphorus and other solid solutions Quench in oil after 30 minutes at 1,600 deg. C. to effect fine dispersion of the carbide. A similar quench from just above the lower critical (1,370 deg. F.) is then necessary to prepare for the spheroidizing, which is effected by 1-hour stay just below the transformation range (furnace cooled from 1,300 deg. F.). This treatment gives a test-bar having ultimate 98,550 lb. per sq in., yield point 65,990, elongation 19.5 per cent, contraction 26.2 per cent and Brinell hardness of 196 Practically the same result, except that the contraction is about 20 per cent, may be had if the hardening treatment be omitted.

Commercial Furfural— Its Properties and Uses—I

Part I of a Paper Describing This Laboratory Curiosity Which Has Lately Become an Important Industrial Aldehyde — Its Occurrence, Manufacture and Properties

By Carl S. Miner, John P. Trickey and Harold J. Brownlee
The Miner Laboratories, Chicago, Ill.

FURFURAL occupies an anomalous position in the realm of chemistry. It was first prepared nearly a hundred years ago and for forty years it has been utilized in a standard and widely used analytical procedure. Yet furfural itself has remained until very recently a chemical curiosity, its chemical properties and even its very appearance practically unknown even to many who have frequently utilized its services in the determination of pentoses and pentosans. A considerable number of years ago, the senior author of this paper had occasion to make several hundred pentose determinations within a few months. Yet despite the fact that in each of these determinations he made furfural by boiling the carbohydrates with acid, distilled that furfural and precipitated it with phenylhydrazin, not once did he see any furfural, since, because of the solubility of furfural in water, no separation of it occurs during the distillation process. The general lack of knowledge of or interest in furfural on the part of the chemical profession becomes the more comprehensible when we realize that it has never been quoted at less than $6.50 per lb. until very recently. Such a price has not encouraged laboratory experimentation nor any important commercial utilization.

Very recently the processes for manufacturing it have been developed to a point where it now sells for substantially less than benzaldehyde and current developments are such that one may confidently predict an ultimate price materially below that at which formaldehyde is now sold. Since it bids fair eventually to become the cheapest aldehydic body commercially available, it has seemed expedient at this time to present a summary of the present state of knowledge of furfural together with the bibliography of the subject which we have thus far compiled. Our own difficulty in finding information to aid us in our investigation of possible uses for the compound leads us to hope that the publication of this information may be helpful to the workers in this field during the formative period of what seems likely to become an important branch of American chemical industry.

Occurrence and Preparation

Furfural was first obtained by Dobereiner (1)* in 1830 while preparing formic acid by the action of sulphuric acid and manganese dioxide on sugar. During the distillation he noticed that the distillate came over milky and on standing, a yellow "oil" separated out. He succeeded in obtaining only a small amount, not enough to make any extensive investigation of its nature. The "oil" was described as having an odor similar to a mixture of oil of bitter almonds and oil of cinnamon and was given the name "artificial oil of ants." A short time later Emmet noticed that an oil" was obtained when formic acid was prepared from rye or corn by treating with sulphuric acid.

Stenhouse (2, 6) in 1840 was the first to prepare any quantity of this "oil." He used Emmet's process for preparation of formic acid, using oatmeal and sawdust as the material from which to make the "oil." He succeeded in obtaining a yield of an ounce from twelve pounds of meal. The composition of the "oil" was determined and formula of $C_5H_4O_2$ given to the compound. This formula has been shown by subsequent investigation to be correct. The effect of treating it with acids and alkalis was studied, and its boiling point, specific gravity and solubilities in water and alcohol determined. Comparison of these constants with those determined more recently indicate that Stenhouse was working with a very impure product.

Fownes (3) in 1845 was the next to work on an "oil" obtained by distillation of bran with sulphuric acid. He found this to be identical with the "oil" studied by Stenhouse and suggested the name furfurol (furfur-bran, oleum-oil). Ultimately, when the aldehyde nature of the compound was established, it became known as furfuraldehyde, which is now ordinarily abbreviated to furfural. He also prepared the ammonia compound to which he gave the name furfurol amide (now furfuramide). The formulas for the two compounds were determined as $C_{15}H_6O_6$ for furfurol and $C_{15}H_6NO_3$ for furfurol amide. He also prepared a compound from the amide which he named furfurin and having the formula $C_{30}H_{12}N_2O_6$. Cahours (7) also obtained furfural from wheat by sulphuric acid distillation and prepared the amide and furfurin. Stenhouse in 1850 (6) prepared "oils" from various vegetable sources and found that these "oils" were similar, but from some classes of vegetable growth, especially seaweeds, there was an "oil" obtained which he claimed was an isomer of furfural and to which he gave the name fucusol. This compound gave an ammonia compound, fucuscamide, and from this by action of dilute potassium hydroxide fucusin could be prepared. In later papers further study is made of fucusol and an acid is prepared analogous to the acid obtained by oxidation of furfural, pyromucic acid, to which he gave the name β-pyromucic acid.

Maquenne (15) and Tollens proved the fucusol of Stenhouse to be a mixture of furfural and methyl furfural. This is the first record of differentiation between furfural and methyl furfural, the product formed by hydrolysis of methyl pentosans.

Many others worked on furfural preparing it from a wide variety of materials such as cane sugar (4), wood (10), glucose (22), and albumen (21), and eventually it was found that pentoses and pentosans were the substances ordinarily yielding furfural, although in a few cases such as glucose, cane sugar, etc., furfural is produced in very small quantities from carbohydrates other than pentoses.

Neff, in his investigations of the actions of various oxidizing agents on glucose, has isolated a series of acids containing 1, 2, 3, 4, 5 and 6 carbon atoms. This reaction is not progressive, the acids being formed

*Numbers in parentheses refer to the bibliography which will be found at end of the second installment, to be published in *Chem. Met. Eng.*, Aug. 23, 1922.

simultaneously. This phenomenon explains satisfactorily the fact that small amounts of furfural are produced by action of sulphuric acid on the hexoses. Sulphuric acid, being an oxidizing agent, first oxidizes the sugar to a five-carbon compound and from this the furfural is probably derived.

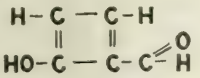
It has been shown that some proteins, especially the nucleo proteins, contain pentose groups, a fact which offers an explanation of the reported production of furfural from "albumen."

It was also found that furfural may be prepared by distillation of pentosans with concentrated solutions of zinc chloride, calcium chloride (5) and other acid salts, as well as by dry distillation. Furfural has been found in commercial fusel oil (109), glacial acetic acid (9), and sulphite-waste-liquors (19). In the case of fusel oil, the furfural was not the product of normal fermentation, but was found to be due to the action of certain acids on solids of the mash during distillation (17).

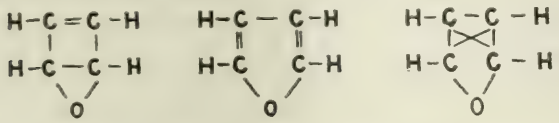
It may be noted that all the products in question where furfural occurs as an impurity have been subjected during the process of manufacture to conditions where a mixture of carbohydrates and acid may have been acted upon by heat.

Structure of Furfural

Limpricht (29) in 1869, by studying the actions of the furfural group with bromine, chlorine, etc., proposes the formula



Baeyer (30) proposes the formulas

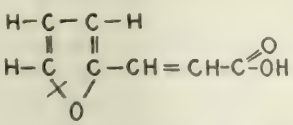


and from the results of his work considers formula 1 as representing the formula of the furfurane group.

Pawlinoff (31) by means of the zinc ethyl reactions established the non-presence of any hydroxide group and favors formula 2 of Baeyer. Markwald prepared a keto acid from furfuracrylic acid having the formula

$$HOOC - CH_2 - CH_2 - CO - CH_2 - CH_2 - COOH$$

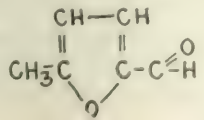
proving the position of the ketone group and concluded that the structure of the furfuracrylic acid is



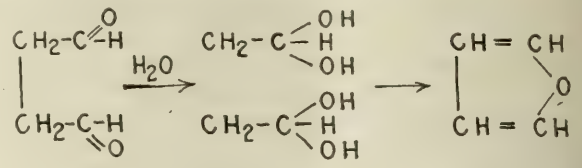
The break in the ring comes at the place indicated, in the forming of the keto acid. Tollens (35) and Maquenne (15) determined the structure of methyl furfural by its derivation for isodulcite

$$\underset{4}{CH_2} - \underset{3}{CHOH} - \underset{2}{CHOH} - \underset{1}{CHOH} - CHOH - CHO$$

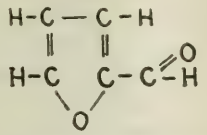
an anhydride being formed by the dehydration of the two alcoholic groups 1 and 4 to give the formula



Harris synthesizes furfurane by heating succinic-dialdehyde with water as follows:



From this evidence the formula for furfural has been accepted as



Manufacture

Until very recently furfural has not been manufactured in commercial quantities and although a number of methods of producing it have been proposed at various times, so far as we are able to learn very few of these have ever been practiced. In the case of those who have actually produced furfural on a commercial scale, very little publicity has been given to the methods used. We can only judge from such uncertain data as the patents issued to them or their published work. On this basis there is some reason to believe that much of the furfural which has been imported has been made from kapok waste by a method which, in a general way, approximates the laboratory procedure for the determination of pentosans, which consists in boiling the pentose-bearing material with 12 per cent hydrochloric acid and distilling. In this country, the excellent research conducted by the Bureau of Chemistry has developed a method not yet utilized commercially so far as we are aware, in which corn cobs or similar materials are treated in a stationary digester at comparatively high pressure without the introduction of acid. We understand that this process has been operated successfully on a semi-commercial scale in connection with the bureau's experimental work.

Our own investigations in this field have led us to select oat hulls as the most readily available raw material for the process, since they are produced continuously throughout the year in large quantities (as much as 200 tons a day at a single plant) by factories centrally located and in a form convenient for treatment. We have developed a simple and effective procedure in which the hulls are subjected to the action of steam and acid in large rotary digesters. By this method very satisfactory yields are obtained and the furfural is produced admixed with relatively small quantities of water. This process is now being operated successfully in a commercial production of furfural amounting to several tons per month, which production will be very greatly increased in the near future.

Since the theoretical yield of furfural from oat hulls is in the vicinity of 20 per cent and the annual production of oat hulls in the United States 220,000 tons, the possibilities of production of furfural from this source alone are enormous.

Chemistry of Furfural

In the following, a rather brief survey of the work done on the compounds of furfural has been made. Our endeavor has been to present a few of the typical examples showing in a general way the types of reac-

ions into which furfural enters and the chemical nature of the compound itself. In the bibliography appended, a much larger number of references will be found than are cited in the body of the paper.

But very little work has been done on the physical properties of furfural. Its boiling point has been determined by a number of workers with varying degrees of accuracy. Probably the most exact results are those of Mains, of the Bureau of Chemistry, recently published in *Chemical and Metallurgical Engineering* (260). Working on a highly purified product, he found the boiling point as 161.7 deg. C. at 760 mm. Its specific gravity was also determined by Mains as $1.1598^{\frac{20}{4,\ Vac.}}$ and $1.1545^{\frac{25}{4,\ Vac.}}$. Its solubility in water and the composition density tables at 20 and 25 deg. C. he determined up to the saturation concentration. The solubility data are reproduced in Table I.

TABLE I—OBSERVED DATA ON MUTUAL SOLUBILITY OF FURFURAL AND WATER

Water Layer		Furfural Layer	
Temperature, Deg. C.	Per Cent Furfural by Weight	Per Cent, Deg. C.	Per Cent Furfural by Weight
16	8.12	8	96.5
17.0	8.18	26.6	94.6
27	8.72	37	93.3
27.2	8.72	44	92.8
27.5	8.68	65	90.9
44	9.80	70	90.3
61	11.9	84	88.0
66	12.5	96	84.5
92	17.0	....	....

Bruhl (80) determined its refractive index with the following results:

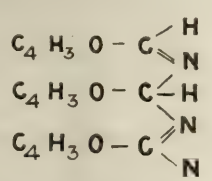
$$\mu_\alpha = 1.51862$$
$$\mu_D = 1.52608$$
$$\mu_\beta = 1.54566$$
$$\mu_\gamma = 1.56484$$

Sir W. Ramsay determined its heat of formation as ,985 cal. The flash point of furfural is 55 to 57 deg. C. Other physical constants of furfural are now the subject f investigation by several workers whose results will e published shortly.

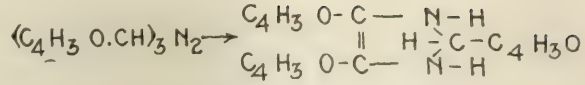
In general it resembles in its reactions benzaldehyde n one hand and formaldehyde on the other. It differs rom both of them in being a liquid of very high boilng point and wide range of solvent power.

It was early discovered that furfural had many chemcal characteristics in common with benzaldehyde, which ed to a rather extensive study of its reactions with arious aliphatic and aromatic compounds as well as he study of the reactions of furfural with ammonia, ydroxylamine, etc.

Among the earliest compounds prepared was fururamide. Stenhouse, Maquenne, Fownes and others repared the compound, but its structure was first deternined by R. Schiff to be



As the corresponding benzaldehyde ammonia compound is converted by treatment with dilute alkali solution into benzin, Bahrmann, Schiff and Cahours prepared furfurin by similar treatment. Bertaginini (129) repared furfurin by simply heating furfuramide at 110 to 120 deg. C. for about an hour.



This compound is much more basic than furfuramide, forming well-defined salts with acids and being alkaline to indicators. Ramsay (89) established that furfurin was a secondary base with two replaceable hydrogens.

By the same method that benzaldehyde, by treatment with alcoholic KOH, is converted into benzylalcohol and benzoic acid, Schiff (97) and Limpricht (99) prepared pyromucic acid and furfuralcohol.

$$2C_5H_4O_2 + KOH \rightarrow C_5H_6O_2 + C_4H_3O.COOK$$

Pyromucic acid was also prepared by oxidation of furfural with silver oxide (96). Furfuralcohol prepared by reduction of furfural with sodium amalgam (95)

$$C_4H_3O.CHO \rightarrow C_4H_3O.CH_2OH$$

Furfurnitrile is prepared by action of PCl_5 on pyromucicamide (94)

$$C_4H_3O.CONH_2 + PCl_5 \rightarrow C_4H_3O.CN + POCl_3 + 2HCl$$

The nitrile by reduction with zinc and H_2SO_4 to furfurylamine (94)

$$C_4H_3O.CN + 2H_2 \rightarrow C_4H_3O.CH_2.NH_2$$

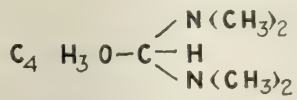
E. Fischer (88) prepared furoin by action of KCN in alcoholic solution on furfural.

$$2C_4H_3O.CHO \rightarrow C_4H_3O.CO.CH(OH).C_4H_3O$$

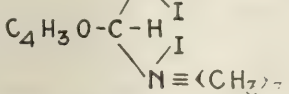
This compound oxidized gives furil, $C_4H_3O.CO.CO.C_4H_3O$. Fischer also prepared mixed compounds such as benzfuroin, $C_4H_3O.CO.CH(OH).C_6H_5$, etc. Furfural forms condensation products with urea and related compounds.

The reactions of furfural with aliphatic compounds have been rather extensively studied. Priebs (237) studied the condensation of nitromethane in alkaline solutions preparing furfurnitroethylene, $C_4H_3O.CH:CHNO_2$ and from this compound by ordinary nitrating methods prepared nitrofurfurnitroethylene, $C_4H_2O(NO_2)(CH:CHNO_2)$, which on oxidation gave nitromucic acid, $C_4H_2O(NO_2)(COOH)$.

Litterscheid (236) prepared furfuryliden-methylamine, $C_4H_3O.CH:NCH_3$, by the action of furfural on methylamine, also the compound furfurylidentetramethyldiamine



Both of these compounds form salts with acids and addition products with alkylhalides such as



Claisen (233), Mehne (232) and Schmidt (231), prepared condensation products of furfural with acetone and acetaldehyde such as: Furfuracrolein, $C_4H_3O.CH:CH.CHO$; furfuralacetone, $C_4H_3O.CH:CH.CO.CH_3$; difurfuralacetone, $C_4H_3O.CH:CH.CO.CH:CH.C_4H_3O$; as well as mixed compounds such as benzal-furfural-acetone, $C_4H_3O.CH:CH.CO.CH:CH.C_6H_5$

Claisen (226), Hill (228), and Markwald (227) condensed furfural with acetic acid forming furfuracrylic acid, $C_4H_3O.CH:CH.COOH$, and studied the halogen compounds of the acid.

Claisen (211), Knoevenagel (224) and Sandelin (207) condensed furfural with acetaceticester forming

$$C_4H_3O.CH:C(CO.CH_3)(CO.OC_2H_5)$$

Furfuralacetaceticester

$$C_4H_3O.CO.CH(CO.CH_3)(C_4H_3O.CH)$$

$$C_4H_3O.CO.CH(CO.CH_3)(C_2H_5O.CO.CH.CO.CH_3)$$

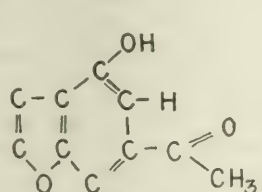
Furfurylidenbiacetaceticester

By condensation of furfural with levulic acid, Ludwig (206), Kehrer (205) and Erdman (86) prepared

$$C_4H_3O.CH:C(CO.CH_3)(CH_2.COOH)$$

β-furfuryl-levulic acid

which on distillation in a current of H_2 or CO_2 condenses forming



Acetooxycumaron.

Succinic and malonic (154) acids condense with furfural forming compounds of the type

$$C_4H_3O.CH:C(COOH)(COOH)$$

Similar reactions were studied by Rohmer (214), Volander (215), Tonnies (213) and others.

The action of phenylhydrazine, hydroxylamine, barbituric acid and phloroglucinol was studied in relation to the quantitative determinations of furfural, pentoses and pentosans. Tollens, Cross and Bevan, and Unger and Jaeger did by far the most work on this subject.

Furfural condenses with acetophenone (165) to form furfural-acetophenone, $C_4H_3O.CH:CH.CO.C_6H_5$, and furfuryl-di-acetophenone

$$C_4H_3O.CH(CH_2.CO.C_6H_5)(CH_2.CO.C_6H_5)$$

Benzylcyanide (167) condenses with furfural to form α-phenylfurfuracrylicnitrile, $C_4H_3O.CH:C(C_6H_5)(CN)$, which is easily reduced forming

$$C_4H_3O.CH_2.CH(C_6H_5).CH_2.NH_2$$

α - furfur - β - phenyl-propyl-amine

By far the greatest amount of work has been done on the reaction of furfural with the amines and related compounds because of the possibility of developing dyes. As early as 1870, Stenhouse (203) prepared the compound of furfural with aniline and various acids, finding that additional products were formed,

$$C_5H_4O_2.2C_6H_5NH_2.HCl.$$

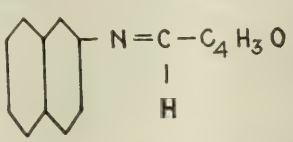
Toluidine behaved in similar manner. H. Schiff (175) supports Stenhouse's reaction and further shows that diphenylamine and *m*-nitraniline react in similar way, forming addition products. However, monomethyl-diamino-benzene follows the regular aldehyde reaction.

$$C_6H_3(CH_3)(NH_2)(NH_2) + 2\,C_4H_3O.CHO \rightarrow C_6H_3(CH_3)(N{=}CH.C_4H_3O)(N{=}CH.C_4H_3O)$$

Benzidene reacts in similar manner, condensation taking place with both amino groups forming

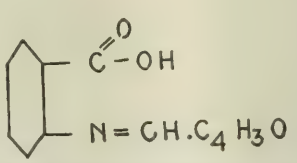
$$C_6H_4.N:CH.C_4H_3O$$
$$C_6H_4.N:CH.C_4H_3O$$

G. de Chalmot (168), however, claims that the reaction of furfural with aniline is a true condensation, the reaction taking place according to the aldehyde-amine condensation reaction. Schiff (170) also studied the action of furfural on various other amines, diamines, tri-amines, as well as acid amines, forming compounds such as



β-furfuronaphtylamine

and

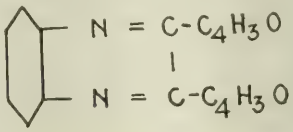


o-furfuramidobenzoic acid

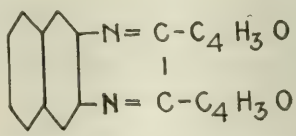
O. Fischer (180) and Schiff (177) studied the analogous reaction to the preparation of malachite green from benzaldehyde and dimethyl aniline forming tetramethyl-diamino-diphenyl-furyl-methane

$$C_4H_3O.CH(C_6H_4N(CH_3)_2)(C_6H_4N(CH_3)_2)$$

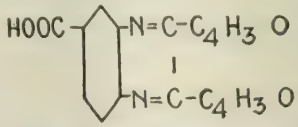
This compound on oxidation forms a dye analogous to malachite green. This reaction has recently been more thoroughly investigated by Renshaw and Naylor and a very satisfactory dyestuff obtained. Fischer (181) also studied the reaction of furoin on *o*-phenyldiamine and α-β-naphthylendiamine forming



and



Zehra (182) prepared a similar compound from 1:2 diamino 4 benzoic acid



Many others have investigated reactions of this type forming many color bases.

It is interesting to note that in spite of the large amount of work done on the chemistry of furfural the

o study has been made of the nature of the chemical action taking place in the formation of resinous condensation products.

Physiological Action of Furfural

But little work has been done on the toxicity or the general physiological action of furfural. Jaff and Cohn (118) studied the metabolism of furfural in dogs, rabbits and hens, and isolated from the excreta considerable amounts of pyromucic acid, a compound of pyromucic acid with glycocoll which they called pyromykuric acid, and a substance difficultly soluble in water which proved to be a glyococoll compound with furfuracrylic acid. Mention is made of the toxic effect, but no specific data are given.

Hugh McGuigan, of the University of Illinois, College of Medicine, has recently finished an investigation on the action of furfural on bacteria, yeast, gold fish, frogs, white mice, rabbits, cats and dogs. The results of this investigation will be published shortly in the *Journal of Pharmacology & Experimental Therapeutics.* Dr. McGuigan has kindly communicated to us the results obtained, which briefly are as follows:

1. The phenol coefficient of furfural, measured from its bactericidal action, is 0.26.

2. A 2 per cent solution of furfural entirely inhibits the action of yeast on dextrose. A 1 per cent solution only delays this fermentation. Weaker solutions have no effect.

3. Furfural is about one-half as toxic for gold fish as phenol and about one-third as toxic as formaldehyde for the same animal.

4. Furfural in large doses has a paralytic effect on frogs similar to chloral. There are evidences of stimulation of the central nervous system when smaller doses are used, but this is more marked in cats. Locally it is corrosive and anesthetic.

5. The fatal dose by stomach for rabbits is about 0.8 c.c. per kg. of body weight. The action on white mice is similar to that on rabbits.

6. In the case of cats, 0.12 c.c. is the fatal dose and with dogs the action is similar.

Part II of this paper, describing the varied uses of furfural and including a complete bibliography on the subject, will appear in Chemical & Metallurgical Engineering for Aug. 23, 1922.

Legal Notes

By Wellington Gustin

Buyer of Patented Welder Recovers Expense of Infringement Suit

In an action at law brought by the Lalance & Grosjean Manufacturing Co. against Neil Macneale and others, directors of the Toledo Electric Welder Co., judgment of the District Court in favor of plaintiff has been affirmed by the United States Circuit Court of Appeals. (276 Federal, 491.)

The action arose from the following transaction. In 1915 the Toledo Electric Welder Co. sold the Lalance & Grosjean Manufacturing Co. three spot welding machines of different sizes and specifications under the following terms and conditions:

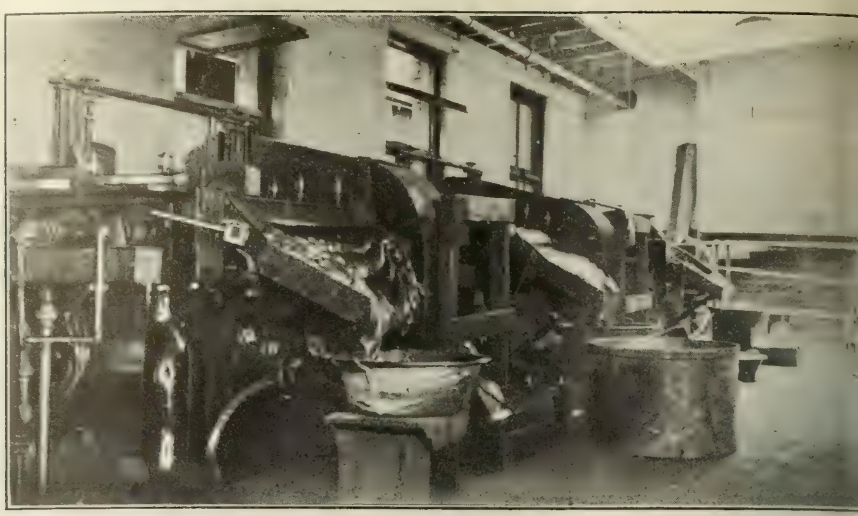
The company agrees that it shall, at its own expense, defend any suits that may be instituted by any party against the purchaser for alleged infringement of any electrical or mechanical patents relating to the machinery furnished under this proposal, providing the purchaser shall have made all payments then due therein and gives to the company immediate notice in writing of the institution of such suits, and permits the company, through its counsel, to defend the same, and give all needed information, assistance and authority to enable the company to so do, and thereupon in case of final award of damages in such suit the company will pay such award." Afterward, in 1917, the American Electric Welding Co. and the Thompson Electric Welding Co. filed a bill of complaint in the U. S. District Court against the Lalance & Grosjean Manufacturing Co. for the infringement of the Harmatta patent, No. 1,046,066, and the latter company was forced to pay $6,572 in defending this suit. The present action was brought to recover of defendants this amount, and also sought to recover in this same action money expended by it in defense of an action brought by the American Welding Co. against the Jordan Marsh Co. of Boston, Mass., one of its customers, for a like infringement; but the District Court held it not entitled, under the terms and conditions of its written contract, to recover the expense of that suit, and it made no appeal from this minor decision.

Although defendants were given notice of the infringement suit over the Harmatta patent, they neglected and failed to defend as per the agreement, and plaintiff was forced to defend. In this action to recover their costs and expenses of defending the suit, the defendants contended as a defense that the machines sold were adapted to other uses which did not infringe the patent sued on; and further that the suit was based on the product of the machines and not on the machines themselves; and still further that the suit was dismissed on objections to jurisdiction and not on the merits.

But the Court of Appeals has held that none of these propositions is a good defense under the provision of the contract as above set out. The contract does not call for defending suits for actual infringement only, but for "alleged infringement."

Another feature in this action was the fact that the Toledo company had been dissolved and its assets had been distributed to the stockholders. The defendant directors contended that they had no money of the company at their disposal to pay the expense of such defense in the infringement suit. Nevertheless, the court said that as directors of the Toledo company at the time that corporation was dissolved the said directors became and were trustees, not only for its stockholders but for creditors, of the assets coming into their hands as such directors. If they distributed these assets to its stockholders before the payment of its creditors or the performance of the obligations of its contracts, they did so at their own risk, and accordingly were held personally liable in this action. They knew or ought to have known that it was the duty of the company under its contracts to defend and pay damages awarded and, being in control of the corporate assets, they should have applied same to this purpose.

Manufacture of Printing-Inks



By Taylor W. Anstead
Dry Color Department, Ault & Wiborg Co.

PRINTING-INK may be said to consist primarily of varnish and pigment, together with a considerable measure of applied research and technical experience. These factors are intimately related, since the quality and properties of the finished ink are largely determined by the fineness, shade, strength and body of the raw materials. Although actual manufacturing experience has shown that for efficient production the varnish, pigment and ink-making should be conducted in separate departments, it is nevertheless essential that the efforts of these departments be closely co-ordinated and frequent consultation should be held, in order that the varnish and pigment makers thoroughly understand and properly interpret the requirements of the ink manufacturer.

It will not be possible within the limits of the present article to present an exhaustive treatment of all of the manufacturing requirements of the printing-ink industry. An effort will be made, however, to refer briefly to those phases of its technology of most interest to the chemist and chemical engineer and to indicate the line along which the industry is developing. This treatment naturally falls under three heads, namely, varnish, pigment and finished printing-ink.

Printing-Ink Varnishes

The manufacture of varnishes for ink-making involves but few features that are not common to the varnish industry. From the chemical viewpoint, a deal of interest attaches to the various varnish oils, principal among which are linseed, chinawood oil or tung oil, soya bean oil, rosin oil, perilla oil and various mineral oils. Linseed oil is by far the most important for varnish making, because of its superior drying qualities, the ease with which it can be "bodied" or "heavied," the better working qualities it gives to the ink, and its good color and pleasant odor.

Many procedures have been outlined by various authorities for determining the quality of linseed oil by means of its specific gravity, iodine number, acid number, etc. But it has been found through practice that these figures are not worth much to the ink maker, and their determination is scarcely worth his while. The writer has found it most satisfactory to make varnish in the laboratory by a standard method and then to test the finished varnish for the properties required of it. Exposure in a drying oven for 2 hours gives its drying value. The varnish should have "flow" and not be "livery"; that is, it should follow the finge after it is dipped into the varnish and not be jelly like. The oil should give a varnish of clear colo with a pleasant odor, and free from sediment.

Chinawood oil has but a very limited application i the printing-ink industry. Its use is confined to appli cations in which unusually rapid drying is essential.

Soya bean oil has come to be regarded as an im portant substitute for linseed oil in certain of the in dustry's requirements. It is used either alone or i mixtures with linseed oil, especially at times when th price of linseed oil is exceedingly high. Although i is the best of the semi-drying oils, it cannot be sai to be as satisfactory as linseed as a varnish oil.

Only recently has perilla oil become a factor in th ink industry. It is imported from China, is practi cally odorless and has a good color. It has most of th good qualities of linseed oil, as far as drying an thickening are concerned. The great disadvantage t its use has been the fact that shipments are not uni form in character and therefore the quality of the oi is not absolutely dependable.

Rosin oil is obtained by the destructive distillatio of ordinary rosin and is marketed as first, second, thir and fourth run rosin oil. The oil ordinarily used fo varnish-making is the first run. Varnishes made fro it cannot, of course, be used on bright pigments, bu rosin oil makes excellent varnishes for black ink especially when treated to obtain drying qualities.

Mineral oils of various kinds are used as varnishe in very cheap inks where a porous paper stock is use They also find application as thinners in higher-grad inks in connection with rosin and linseed oils.

Treating the Oils

Linseed oil, as such, when ground with a pigmen would give a sloppy ink; it must therefore be thick ened or bodied to give an ink of satisfactory workin qualities. The raw linseed oil, which has about th fluidity of water, can be bodied through various inte mediate stages to the consistency of molasses taff The various bodies are numbered as a rule from a 000 for the lightest to No. 7 for the heaviest of the boile or blown oils. In the boiling process the linseed o is heated in a copper kettle over a gas, coal or oil fir the temperature and time varying with the grade t be produced.

In blowing linseed oil, air is bubbled through the o

ntil the desired body is obtained. The advantage laimed for blown oils is a lower acid value and there- ore better drying qualities. However, this better dry- ng is offset by the fact that blown oils do not mix s easily with other oils and varnishes, the color is ot so good, and they will not lithograph as well as he varnishes made by external heating.

In making rosin-oil varnishes, the first run oil is sed because it is of a heavier body at the start and he varnishes made from it have greater drying quali- ies. Rosin oil is heated and then about 1 per cent f its free rosin acids are neutralized with lime. If nore is neutralized the varnish dries too rapidly and s likely to form an oxidized film or skin. A more uni- orm drying can be obtained by adding a small quan- ity of some drier such for example as about 2 per ent of lead and manganese resinates.

Driers and Retarders

A drier, it will be recalled, is a substance which when dded to a varnish acts as an oxygen carrier and thus ccelerates the oxidation of the varnish and causes t to dry. The action of these driers is purely atalytic.

In contrast to the driers there are substances which ct as negative catalysts and actually prevent drying. Among these the most notable is selenium, the presence f a small amount of which retards drying to an extent ut of all proportion to the quantity present. Recent xperiments would seem to indicate that to a lesser xtent the presence of sulphur in carbon blacks will etard their drying. Blacks which are free from sul- hur dry much more readily than blacks which contain hat element. It is a well-known fact that pigments ade from basic dyes are notoriously poor driers and xcess drier has to be added to the inks.

The driers in most common use are the linoleate, esinate and tungate of lead, the borate and resinate f manganese, and the acetate and resinate of cobalt. he drying effects of vanadium compounds, especially mmonium vanadate, have been referred to in a recent rticle by Rhodes and Chen[1], but their activity has een placed below that of cobalt. Furthermore their ost at present is prohibitive.

Each metallic drier may be said to have a different se depending upon its drying qualities. Cobalt is the est drier. Its action is to dry quickly on the surface, iving a hard film. It is surprising how small a quan- ity of cobalt, calculated as the metal, is necessary.)ne hundredth of one per cent will often dry an ink atisfactorily. Manganese dries peculiarly in that the nk remains raw for some time and then suddenly ardens. Lead dries gradually and ink in which it is sed is inclined to be rather sticky. Manganese and ead together, however, will give a well-balanced drying ffect.

Few people realize that the drying of an ink is not ndependent of the paper stock on which the ink is to e used. The oxidation which occurs is not only af- ected by the metallic driers but also, either positively r negatively, by the fillers and pigments used in mak- ng the paper. Too often the ink-maker is kept in gnorance of the kind of paper on which his ink is to e used. He tries to meet an average condition and requently has his ink returned because it has not ried properly, when the fault lies in the paper.

[1] F. H. Rhodes and K. I. Chen, *J. Ind. Eng. Chem.*, vol. 14, pp. 22-4 (1922).

Ink Pigments

In the manufacture of printing-inks two general classes of pigments are used (exclusive of carbon blacks)—namely, the natural or earth colors and the artificial colors. To the former class belong the ochres, umbers and siennas; to the latter class, the organic lakes, the chrome yellows and the iron blues.

The natural colors are noted for their fastness to light and for their resistance to alkalis, acids and bleaches. However, they are not easily worked, do not cover well, have a tendency to fill up the plates, and have little tinctorial value. On the other hand, the manufactured colors yield an infinite variety of shades, have great color strength and work well in varnish. Many of them, too, are comparatively fast to light and to the action of acids and alkalis.

Organic Color Lakes

In making an organic lake the manufacturer attempts to render the dye as insoluble as possible. This is done by treating the soluble dye with barium or calcium chloride, thereby forming the barium or calcium lakes of the dye, which in nearly all cases are insoluble. Or in place of the soluble dye an insoluble product may be formed by the combination of intermediates such as the formation of the para reds by the coupling of diazotized paranitraniline with beta-naphthol.

Most organic lakes have too high a tinctorial value to be used as such. Besides, they do not give as good working qualities as when diluted with an inert base. The 100 per cent color lakes are known as toners and the diluted colors are referred to in terms of the percentage of pure color present.

Bases for Color Lakes

The usual bases for printing-ink colors are blanc-fixe, aluminum hydrate or a mixture of the two. Blanc-fixe is used as the base for the cheaper colors designed for poster or bag inks. The artificial barium is preferred to the naturally occurring barytes, which is very rarely used in printing-inks because it is gritty. Blanc-fixe is of two kinds, the precipitated and the byproduct material. Experience has shown that the byproduct blanc-fixe is usually unsuited for lithographic inks because of its action with water. The ink from such a lake becomes pasty because of its water absorption or, in exaggerated cases, it may literally "go to pieces" and break down entirely. Precipitated blanc-fixe should be white, neutral and free from sulphides. Sulphides very often give trouble in connection with copper plates or when the blanc-fixe is mixed with a lead chromate yellow.

Aluminum hydrate is very transparent and is therefore suitable for process inks where one color must be seen through the color above it. Great care must be exercised in the manufacture of aluminum hydrate for color lakes. It is ordinarily prepared from aluminum sulphate and soda ash. The former should be free from iron, since ferric hydroxide gives the aluminum hydrate a dirty, brownish color. Precipitation is best effected in dilute solutions, 10 per cent or less, because too great a concentration is likely to give a product which dries out too much. The base should be carefully washed to free it from soluble sulphates, as these are likely to give trouble in lakes precipitated with barium chloride where the presence of barium sulphate would throw the color toward the semi-transparent

side. The writer has observed batches of color made from the barium lake of lithol red where the addition of poorly washed aluminum hydrate has caused the lake to lose its bluish shade and take on a yellower shade due to the barium leaving the dye and combining with the free sulphate in the hydrate.

A base which is quite popular is a mixture of blanc-fixe and aluminum hydrate. In this base, the advantage of the comparatively low cost of the blanc-fixe is combined with the high finish and luster given by the aluminum hydrate.

Para and Toluidine Reds

The red organic lakes present the greatest variation in color from the yellow-red, almost orange shade, of a light para red to the deep blue shade of the eosines. The good old standby of the ink-maker, as of the paint-maker, is paranitraniline red. The light shade is produced by combining diazotized paranitraniline with beta-naphthol. The deep shade is produced—and here is one of Nature's mysteries—by the addition of about 5 per cent of beta-naphthol monosulphonic acid F to the beta. Paranitraniline gives nothing like the same shade with F acid alone; the shade results only when the color is heated and furthermore, the addition of too much F acid is likely to throw the color over to the brown side and cause it to lose its blue tone entirely.

The para reds are popular because of their good working qualities, the comparatively low cost of the intermediates entering into their production, their relative fastness to light and to the action of acids and alkalis.

A color of even greater permanency is toluidine red from diazotized meta-nitro-paratoluidine and beta-naphthol. The cost of the former intermediate makes its use not quite so common. An interesting incident grew out of the attempts of the writer to improve upon the quality of the post-war toluidine reds. The laboratory results were fine and bright and so too were the results on the semi-plant scale tests, but the first four or five large plant batches were miserable failures. Temperatures were checked, dilutions were checked, materials were checked, but to no avail. Finally the only difference that could be seen was that lead brine coils were being used to cool the diazo solution, whereas ice had been used in the laboratory and the semi-plant operation. In the next run ice was therefore used and the diazotization was carried on in a vat free from lead. The results were all that could be desired.

Lithol Reds and Eosine Lakes

Next color in importance to the toluidine reds are the lakes made from lithol red, which is a combination of Tobias acid (2-napththylamine——1—sulphonic acid) with betanaphthol. The sodium salt is used alone or diluted with white to give a yellowish red; when the sodium salt is boiled with barium chloride a bluer shade results. Treatment with calcium chloride produces a very deep, bluish red. An interesting fact to be noted in connection with the lithol colors is that the calcium lake will stand baking, whereas the sodium and barium lakes will not. In purchasing the dye, care must be taken to see that it does not give lakes which "bleed" in oil. This bleeding is due to the presence of beta-naphthylamine arising from the use of impure Tobias acid. Lithol reds now appearing on the market as a rule are free from this objectionable feature. This oil-bleeding is a serious defect in fine printing because the color will strike through with the oil and can be seen to stain the reverse side of the paper.

Eosine lakes are used to a considerable extent in process work where a very pure red of bluish hue is desired. The lakes can be prepared from eosine by precipitation with lead nitrate or lead acetate, but it is more economical to prepare them from the bromo acids. Eosine is the sodium salt of tetrabromo-fluorescein, whereas the bromo acid is the acid of the same compound. If the acid is used it is first dissolved in alkali and then re-precipitated as the lead salt. Experience has shown that greater strength is to be had from the bromo acid than from the corresponding eosine. Bromo acids are to be had in two classes, the boiling bromos which are precipitated and boiled and the non-boiling bromos which are struck at lower temperatures. The first class gives a bronze red while the second class gives a red of dark overtone and more transparency.

These are the main divisions of the reds, though many others might be named. In fact, a well-equipped printing-ink concern uses 20 to 25 different red pigments. Unfortunately it seems to be a rule with red pigments that the stronger and brighter the color the less permanent it is to light. For instance, the bright clean eosine and rhodamine lakes are very fugitive with light, whereas the duller para reds and madder lake are comparatively permanent.

Blue Pigments

The blue pigments used in the greatest quantity are the so-called iron blues. They vary in shade from a greenish blue to the blue of a reddish, almost purplish cast. Before 1914 nearly all the blues were made from potassium ferrocyanide, either alone or in combination with sodium ferrocyanide. The impression existed in pre-war days that good blues could not be made from prussiate of soda. However, that impression was speedily removed from necessity when the supply of potash was cut off and it was not long before the American dry-color maker learned that very good blues could be made from prussiate of soda. Even now when prussiate of potash is available, the soda blues have not lost their popularity.

Ultramarine blue, another pigment of great utility because of its cheapness and resistance to alkali, has reached a perfection in this country never known before, even among the products of the best of the European makers.

The only blue lake used to any great extent is peacock blue, the barium lake of patent blue. This is used largely in process inks on account of its pure blue tone. The peacock blues of war times and post-war times were not very satisfactory.

The product was helped some by imported dyes, but now the American manufacturers are making very good patent blue.

Other Ink Pigments

The yellow pigments in greatest demand are the chrome yellows made from sodium bichromate and lead acetate. To a basic lead acetate solution is added a bichromate solution containing sulphuric acid. The lead chromate formed varies all the way from a light lemon yellow to an orange depending on their reaction

The light yellows show an acid reaction, the medium yellows are practically neutral lead chromate, while the orange yellows are made by boiling the precipitated lead chromate with caustic soda or soda ash, thereby forming the basic lead chromate.

Yellow lakes from the barium precipitation of acid yellow dyes are used where a transparent yellow is desired in contrast to the opaque chrome yellows.

Most of the purples and violets are made from methyl violet which can be had in a great variety of shades from the very red (R) to the very blue (6 B). Where brilliancy of color and no great amount of permanency are required, the usual method is to precipitate the methyl violet with tannic acid and tartar emetic. However, under patents now licensed by the Chemical Foundation, violet lakes may be produced from methyl violet by precipitation with sodium tungstate or with phosphotungstic acid. This increases the permanency of the violet lakes to a remarkable degree and raises them from the "fugitive" to the "semi-permanent" class. The peculiar thing about the lakes so produced is that when acted upon by light they turn darker. This increased permanency may be extended to some of the other basic dyes like fuchsine, malachite green, and Victoria blue, but the lakes of these dyes have not the variety of application that the purple lakes have.

Manufacturing Kinks

In the manufacture of pigments a good washing is necessary because the salts formed on drying down with the pigment not only reduce the strength but are likely to affect the ink, especially when intended for lithographic purposes where the action of the salts with the water may destroy the working qualities of the ink. Drying must be watched closely in pigment making.

Some colors are very readily affected by heat and it is better in most cases to dry for a longer time at a low temperature than to heat too high in order to speed up drying. About 160 deg. F. is a very good temperature for the drying ovens. The general scheme is to draw air through coils heated by steam. This heated air then passes over the color, which is in thin cakes on drying racks. Exhaust steam from the boilers can be used to good advantage here.

When dried, the color is ground. The finer the color, up to certain limits, the better it can be ground on the ink mill with varnish. About 60 to 80 mesh is the proper fineness. Finer than 80 mesh makes the color too fluffy and causes a great deal of dust and waste. In order to get uniformity the color is ground into large mixers holding 2,000 lb. or more. It can then be strengthened if weak, or cut down if too strong. As a rule a composite of several batches of pigment are mixed at one time, as it is practically impossible to make every batch of pigment identical and this method strikes a good average. Standards for comparison purposes should be taken the same way. Too often the enthusiastic color man, on seeing a remarkably fine batch come through the factory, adopts it as the standard, sends out samples and then has tough sledding to duplicate it, whereas if he had taken an average of eight or ten factory batches he would be nearer the true standard. Another dangerous practice is to send out samples of laboratory lots before they have been duplicated in the plant.

The improvement the last two years in the quality of the dyes and pigments produced in this country has been remarkable. Old standards adopted during the war look dull and muddy by contrast with colors produced with improved dyes and intermediates. Along with the improvement in colors has come an increased discrimination upon the part of the printer and color user.

Ink Manufacture

After the varnish and pigments have been prepared they are sent to the mixing room. Here they are weighed into mixing cans and the color is thoroughly wet with the varnish on a pony mixer. This is a machine so geared that the can turns in one direction while four prongs, dipping into the mixture, turn in the opposite direction. The ink is then sent to the mill room, where it is run over the ink mill. This mill is composed of three steel rollers with carefully ground surfaces, set in a frame. The rolls are usually 9 or 12 inches in diameter. Their highly polished surfaces roll in contact with each other. The ink is fed into the rear roller, which rotates clockwise, and is ground between it and the middle roller, which moves in a counter-clockwise direction. The ink is taken from the front roller by means of the knife-edge of the apron, which fits tightly against the roller. (See illustration.) A great deal of heat is generated during grinding and the rollers are made hollow so that cooling water can be passed through them. Many colors change on grinding if the rolls are not so cooled. The light shade of paranitraniline red will develop quite a bluish shade on grinding or may even turn brown if too much heat is developed.

Proving and Testing

The number of runs through the mill which an ink requires is determined by the pigment. Some colors, like the chrome yellows, are ground in three runs, while the iron blues will often take five or six. The question of determining whether or not an ink is properly ground is largely a matter of experience. An experienced ink-maker can tell by rubbing the ink about under his fingers. Spreading the ink out under a spatula will often show up particles of grit.

As the last run of the ink is coming out of the mill, a small sample is sent to the testing department, where it is drawn down on a sheet of paper against the standard to get the overtone, or mass-tone, and the undertone, or shade. A small portion is then carefully weighed out with an opaque white mixing ink in the proportion of 10 of white to 1 of color; the standard is treated in the same way. This test shows the tinctorial or coloring power of the ink and gives a very good way to determine any fine differences in the shade, since slight variations are easily discernible in the bleach test.

It has been found by experience that whenever possible it is best at this point to make a proof of the lot of ink and of the standard and allow them to stand over night to notice the effect of drying. Any change in shade will likewise be noticed. The body of ink should be examined the following morning, as often an ink will appear to have the right body when warm from grinding, but on cooling over night may become too heavy or may "liver up." A case was recently called to the writer's attention where a green made from an iron blue and a chrome yellow had changed to a decidedly yellow tone over night due to the action of

the paper on the blue. The remedy was to make the pigment several shades bluer.

Printing Requirements

Printing ink is put to such a variety of uses that the ink-maker must use a great deal of discrimination in the choice of his pigments and varnishes, but most especially of the former. For instance, an ink may be wanted for a hand-press, for a flat-bed press, for a rotary press, for offset work, for a bread label, soap wrapper, butter wrapper, poster, bag or bottle. Each use calls for a different body and drying quality of ink and in addition, the coloring matter must have certain properties. One color may be permanent enough for a circus poster but might bleed in hot paraffine and therefore be unsuitable for a bread label, or the color might make a beautiful ink for an art calendar or a book illustration but be utterly useless on a soap wrapper.

The question of fastness to light is of vital importance in many cases. It is a sad day for the billboard advertiser if the ink maker has been careless in the choice of his pigments and after three or four days his advertisements have bleached out or changed color decidedly. Of course, the best test for permanency to weather conditions is to put the color on a billboard for a period of one month. Often quicker tests must be had and resort is made to artificial devices. One of the best of these consists of a constant-arc light surrounded by a metal cylinder containing openings and brackets on which the colors to be tested are exposed. One half of the sheet is kept covered and one half exposed. A pan of water acts as a humidor and with the aid of a fan, which draws a current of air through the apparatus, prevents baking. To simulate atmospheric conditions the proofs are wet every morning. Proofs are left under the light for a time depending upon the conditions which must be met. One hour under this light equals six hours of sunlight. Sometimes a qualitative test of colors to determine the dye used can be made by this exposure test. For instance, a malachite green lake can be distinguished from an acid green lake by the fact that lakes from the former dye turn darker under light, while lakes from the acid green fade out entirely.

Three Classes of Printing-Inks

Printing-inks may be divided roughly into three classes: typographic, lithographic, and depressed surface inks. Typographic inks include all inks for labels, catalog and book work and general job-printing. The inks of this class are much softer and thinner in body than the lithographic inks and in the preparation of them, pigments can be used which "bleed" in water.

Lithographic inks are heavy in body. They are used in the presence of water and therefore must be water resistant. Accordingly great care must be exercised in the selection of varnishes and pigments. Inks which absorb water and become short and greasy are worthless for lithographic work, as they tend to smear and do not give clear-cut impressions. An ink which when rubbed with water on the lithographer's stone becomes pasty or stringy is unfit for use as a lithographic ink.

Depressed surface or plate inks are used for copper-plate engraving, for calling and announcement cards, in making season and greeting cards, and similar examples of fine printing. One kind of ink which can probably be classed under depressed surface ink is rotogravure ink. This type of work, wherein a half-tone effect can be had on machine finish paper, was just coming into prominence before the war. The demand for illustrated material brought this process into great favor as evidenced by the fact that today nearly every large newspaper carries a weekly rotogravure supplement. In this process the design to be reproduced is etched on copper cylinders. These cylinders dip down into the ink and are wiped off by a steel blade, leaving the ink in the depressed surfaces while the high lights have no ink on them. The paper is then passed over the cylinder, and after running about 25 feet, the reverse side is printed. Hence for this type of work ink must be a rapidly drying one.

The highest grade ink of all is the process ink. In this work, three, four and sometimes more colors are superposed upon one another. The colors used in four-color work are yellow, red, blue and black, printed in the order named. Each color except the yellow must be transparent or semi-transparent to get the effects of the colors beneath it. In this way, reproductions of painting are made. A separate plate is made for each color by photographing the painting four times. Each time only the color value desired is photographed the others being kept out by suitable light filters. Colors like green, orange, violet, etc., are formed by combinations of the four principal colors. For instance, blue over yellow gives a green; or a dark purple would be produced by blue over red intensified by black and so on. The colors entering into these inks are of very pure tone and must be of fine grain, otherwise the cuts would be filled up and ragged outlines result. Only the very highest grade linseed-oil varnishes are used in process inks.

The one universal ink is black. There are innumerable kinds of black inks. Blacks which dry by penetration may be made from cheap carbon blacks and mineral oil. Rotary blacks for process work, which dry by oxidation, are made from very good rosin-oil varnishes or linseed-oil varnishes.

New Developments

New developments in printing machinery must be met by the ink-maker. One of the latest improvements is a press doing what is called simultaneous color-printing, that is, three colors are printed, one on top of the other, before the sheet leaves the press. The ink manufacturer is also called upon to meet new conditions arising from change of paper stock or method of working. The printer makes his changes to suit his customer or his purse and then tells the ink-maker to get busy and make an ink to fit his requirements.

It may be seen from this rather cursory review of the materials and manufacture of printing-ink that physics plays as important a part as chemistry. The chemistry of ink-making is comparatively simple even in pigment manufacture, whereas the physical side of the process presents infinite possibilities. Colloidal chemistry, however, is beginning to play an important part in ink-making and many of the ink-maker's difficulties will probably be overcome as our knowledge in this field increases.

Constant research supplemented by the accumulated experience of the ink-maker is the price to be paid for this industry's success.

Effect of Rate of Loading On Tensile Properties Of Boiler Plate

By H. J. French
Physicist, Division of Metallurgy, Bureau of Standards

Effect of Decrease in Rate of Loading on Steel Is Different Above and Below Blue-Heat, but Little Variation in Tensile Properties Was Observed When Tests Were Performed Thirty Times as Fast as Ordinarily

WHETHER or not steel is susceptible to variations in rate of loading at operating temperatures of steam superheaters, crude oil stills or nitrogen fixation apparatus is of decided interest both from practical and theoretical standpoints, especially as there are comparatively little definite data available in the literature.

In his book on "The Manufacture of Iron and Steel," H. H. Campbell reports the tensile properties of structural steel obtained under pulling speeds of 0.07 to 4.5 in. per minute. Both the yield point and tensile strength were shown to increase with rate of loading, while the elongation and reduction of area remained practically constant. The last two are independent of the accuracy of the beam balance; when high pulling speeds are used it becomes increasingly difficult for the operator properly to balance the testing machine and the tendency toward "overbalancing" often results in high values.

A committee of the American Society for Testing Materials[1] has since shown that the tensile properties of steels at room temperature are independent of the rate of extension within limits of commercial practice—speeds of from 1 to 6 in. per minute.

Hot Steel Resists Rapid Loading

Little exact information is available on variations in speed of loading at elevated temperatures. Hopkinson and Rogers[2] reported that the so-called "time effect," "elastische nachwirkung" or "creeping" increased greatly with temperature. While such effects might be detected at ordinary temperatures, they attained a different order of magnitude at red heat (600 deg. C.).

"Creeping" made the determination of Young's modulus a matter of some uncertainty, for the extension of a bar stressed at 600 deg. C. varied 15 per cent or more depending upon the time of application of the load. For rapid loadings—of the order of 1 second—the strain produced approached a definite limiting value which could be used for the accurate determination of the modulus.

J. E. Howard[3] reported that the "rate of speed of testing, which might modify the results somewhat with ductile material at atmospheric temperature, had a very decided influence upon the apparent tenacity at high temperature." Steel containing 0.81 per cent carbon was ruptured in 5 to 10 minutes and also as quickly as from 2 to 8 seconds. Nearly the same strength was displayed whether slowly or rapidly fractured at temperatures below about 315 deg. C. (600 deg. F.), this being a comparatively brittle metal at moderate temperatures. Above this temperature the apparent strength of the rapidly loaded specimens largely exceeded that of the slowly loaded ones; the higher the temperature the wider the spread. One specimen broken in 2 seconds at 766 deg. C. (1,412 deg. F.) showed a tensile strength of approximately 62,000 lb. per square inch, whereas at ordinary speed of testing a corresponding bar fractured at 33,240.

Howard considered that the forces of cohesion tending to prevent rupture in a plane normal or oblique to the direction of the straining force and intermolecular friction developed during the flow of the metal were controlling elements in the explanation of the behavior of steel under the conditions outlined.

More recently Rosenhain and Humfrey[4] have investigated the strength and fracture of soft steel at temperatures between about 600 and 1,100 deg. C. (1,100 and 2,000 deg. F.). They found a discontinuity at the thermal critical range and an increased tenacity with rapid loading when testing small samples in a vacuum.

Apparatus for Rapid Testing

The ordinary method of determining proportional limit by measuring the deformation under successive increases in load is not sufficiently flexible to allow much variation in rate of extension without loss of accuracy. Obviously, it is impossible to read simultaneously several continuously moving indicators, even with a number of observers. Therefore an ordinary testing machine was modified in some essential details so that instruments indicating stress and strain were placed close together where they could be photographed during the test by a motion picture camera. This arrangement has already been described in *Chemical & Metallurgical Engineering* for Jan. 19, 1921 (vol. 24, p. 131).

Load may be applied at any predetermined rate, and while the beam was at all times kept as nearly in balance as possible by the operator, photographs were taken of the three constantly moving dials at the rate of about one a second. The loading was continuous until the bar was broken and no changes in gears or

motor speed were made throughout the test. After development the film was projected on a screen, where images of the dials were enlarged and as much time as was desired might be taken in obtaining individual readings. Under the conditions outlined above more photographs were obtained than required, but these served as an indication of the balancing of the beam; if this is not closely maintained, it results in serious deflections in the resulting stress-strain diagrams.

Moderate Variations in Rates of Loading of Small Importance

A summary of the tests made on railway firebox steel at various temperatures under different rates of extension is given in Table I. The following conclusions may be drawn:

1. The tensile properties of firebox steel at temperatures up to and including the blue-heat range [295 deg. C. (565 deg. F.)] are independent of the rate of loading.

2. At 465 deg. C. (865 deg. F.) the tensile strength appears to increase slowly with rate of loading while ductility as measured by elongation and reduction of area is practically constant.

At this highest temperature the stress-strain diagrams obtained were not satisfactory. The elastic limit is low and is reached soon after the "slack" is taken up in the available geared apparatus. There is, however, a difference in behavior of the metal at or below blue-heat and 465 deg. C. (865 deg. F.) as indicated by variations in the figures for ultimate strength.

Slow Loading

In addition to the foregoing tests, samples of A.S.T.M. firebox plate were broken at about the same temperatures by increasing the applied stress very slowly when passing the proportional limit. The load was increased 100 lb. at 5-minute intervals over a definite range at each temperature and subsequently the test specimen was broken at standard speed. Such slow loading raises the strength and decreases ductility at 156 deg. C. (315 deg. F.), but the steel exhibits decreased strength and higher ductility when so tested at blue-heat or above than when broken in the ordinary manner. Table II contains the figures.

Microscopic Examination

Fractures of steel broken at various temperatures at different rates of loading and under varying conditions of mechanical work were examined under the microscope and were found to be generally transcrystalline. Minor differences appear under certain conditions such as, for example, the apparent tendency for the fracture to follow more deeply along the grain boundaries and particularly at the junctions of ferrite and pearlite when the steel is broken under very slowly increasing stress, but in general no marked differences in behavior were observed.

Tearing Tests on Metals

By Henry L. Heathecote* and C. G. Whinfrey†

THE results of impact tests are sometimes very surprising. A material which may give good results under the tensile test will sometimes give quite the reverse of good results under an Izod impact test. Such test-pieces break like a carrot. The simile is literal; it is not at all easy to break a carrot until the periphery has given way, then it tears across quite easily. This tearing is a point we should like to dwell upon for a few moments.

Metals in structures are figured to resist either tension or shear, and engineers speak of the working stress being so many pounds or tons per square inch. This is convenient and satisfactory so long as that square inch does what is expected of it and carries the load pretty uniformly. But the pious hope that every section will do its duty ought not to close one's eyes to the possibility that some day that whole load may be borne not by the square inch but by a very small part of it. In fact it has recently been shown by Professor Coker that heavy stress concentrations are to be expected in parts where the section changes. Then a load of so many pounds or tons per square inch will become so dislocated as to overstrain the piece badly at the surface and the material will *tear*.

To see this point more clearly consider the behavior of a material possessing no elongation. Such a metal might stand well under static tension and shear; but once a crack started, at the periphery for instance, it would spread right across under a vanishingly small pull for the reason that in such a material the forces at the apex of the crack would be enormously great. Of course, such material is unknown, but many are known which approximate to such a condition.

Some years ago one of us studied the failure of india rubber and observed that although it stood tension remarkably well it *tore* quite easily. A poor specimen required to *tear* it apart only 1/150 part of the energy required to pull it apart. This suggested applying a similar test to metals.

Tested in this way one gets the following results for resistance to tearing:

Thickness Tested, In.	
0.018	Tin plate, 770 to 750 lb. per linear inch.
.015	Brass, as received 651, annealed 530 lb. per linear inch.
.028	Aluminum, 270 lb. per linear inch.
.091	0.40 C steel, 1627 lb. per linear inch.
.018	0.05 C steel, 989 lb. per linear inch.
.013	Copper, 912 lb. per linear inch.
.075	Lead, 220 lb. per linear inch.

We had no difficulty in finding specimens of steel which tore at about 1,000 lb. per linear inch. The energy required to tear 1 sq.in. of such material was about one-fifth as much as to pull a piece 1 sq.in. in two.

Test-pieces for tearing tests have to be cut from thin sheets. The best form we know is made by taking a piece of sheet, about 2x4 in. in area, and slitting it carefully with tinners' snips as shown in Fig. 1. The

*Chief of Research Laboratories, Rudge-Whitworth, Ltd., Bearing Works, Birmingham, England.
†National Lamp Works of General Electric Co., Nela Park, Cleveland, Ohio.

tongue of metal 1x3 in. is turned out square out in front, and the two wings exactly opposite in direction, making a piece as shown in Fig. 2. This bent test-piece is then mounted in a tension machine, one grip taking the tongue and the other the wings. A delicate machine capable of registering accurately loads of a few pounds is required, for even the toughest steel in thickness of a few hundredths of an inch will require only 100 lb. more or less to tear it apart. A machine for testing paper or fabric will usually serve excellently.

Pull is then gradually applied until the metal tears as may be observed under a strong glass. The load is observed and immediately released. Five or six repetitions are made and the average taken for the strength of the metal.

The pull observed is that required to tear metal in two places and bend and unbend a total width equal to that of the specimen. In order to eliminate the work done in bending, it is necessary only to execute a similar test on a narrower or wider test-piece cut from the same material.

If P is the pull required to tear, bend and unbend a piece x in. wide

and p is the pull required to tear, bend and unbend a piece y in. wide

then $P - p$ is the pull required to bend a portion of the piece $2x - 2y$ in. wide

Therefore pull required to bend $2x$ in. $= \dfrac{P - p}{(2x - 2y)} \times 2x$

$$2x = \frac{(P - p)x}{x - y}$$

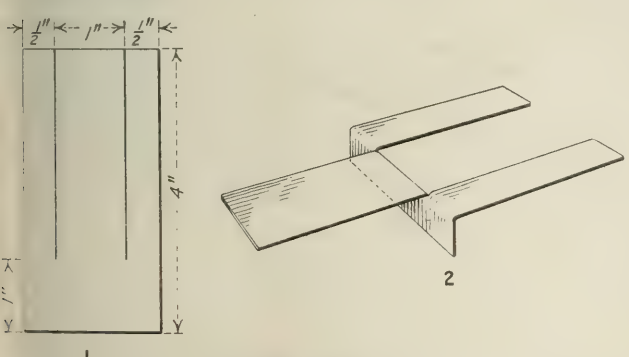
Pull required to tear specimen in two places

$$P - \frac{(P - p)x}{x - y} = \frac{px - Py}{x - y}$$

Tearing force per linear inch $= \dfrac{px - Py}{2t(x - y)}$

Where t is the thickness of the sheet.

It is apparent that the force required for bending will quite overshadow the force required for tearing in a thick piece.



FIGS. 1 AND 2
Fig. 1—Test-piece before bending.
Fig. 2—Test-piece after bending.

So far as we are aware the testing of metals for resistance to tearing is being done only at the Rudge-Whitworth research laboratory, in Birmingham, England.

The impact test on *notched bars* approaches the tearing test more closely than the ordinary tension test does, for the rupture of the metal in notched bar impact is by rapid tearing. By testing two specimens with different cross-sectional areas, it is possible to obtain simultaneous equations and to solve for the energy required to *bend* the test-piece and the energy required to *tear* it. In applying this method to some tests done at the National Physical Laboratory by Dr. Stanton and Mr. Batson, the resistance to tearing of one of the steels tested is found to be 1,580 lb. per linear inch, which is in close agreement with the figure for medium steel already referred to, obtained by tearing a sheet of thin steel and measuring the pull required.

We may reasonably expect tearing tests to throw light upon the suitability of materials for constructional purposes and that they will be of interest to metallurgists in throwing light upon the physical constitution of microstructure of metals and alloys. From the appearance of the fractures which occur during the life of metals in use it is obvious that they are for the most part tear-fractures, or, as they are more commonly called, "fatigue-fractures." Indeed, "fatigue fractures" doubtless start from some internal notch where the stress concentration is above the ultimate strength of the material. Probably all hardened steels break by tearing, as also do high tensile alloy steels such as nickel-chromium steel.

On the other hand, it would not do to assume that resistance to tearing should always be as high as it is possible to make it. When material is machined the ease with which it is removed by the tool depends upon the ease with which it tears apart forward of the tool point; and a high machining speed will be obtained only when the Brinell hardness and resistance to tearing are relatively low.

Calcium Silicide as a Deoxidizer

According to a recent number of *The Iron and Coal Trades Review*, the use of calcium silicide for deoxidizing liquid steel is increasing in favor among English steel makers. This fact is due to the very powerful deoxidizing characteristics of calcium, and will, under conditions where silicon alone is not sufficiently powerful, usually completely deoxidize the metal. Calcium metal has a very powerful affinity for oxygen, and while the oxide, as well as silicon oxide, melts only at extremely high temperatures, mixtures of the two form silicate slags which melt at temperatures existing in the steel furnace. Such slags are insoluble in the metal, rise to the surface, and are easily incorporated in the normal slag, which is of the same nature.

The use of calcium as a deoxidizer under normal conditions should be quite safe, as any excess calcium left in the steel after the reaction is completed will be rapidly oxidized from external sources of oxygen in the surrounding air or volatilized, consequently there is little risk of leaving any trace of calcium in the steel.

Like silicomanganese, it is a ladle addition, and preferably made in powdered form. French alloy containing Si 60 to 65 per cent, Ca 30 to 35 per cent and Al 2 to 3 per cent is mostly used in Great Britain. It is reported that the violence of the reactions cause small explosions to take place if lump material is added to gassy steel. This phenomenon has not been noticeable in American experiments with the alloy.

Two grades are available in the United States, manufactured by the Electro Metallurgical Co. in the electric furnace:

	Grade 1	Grade 2
Ca	24 to 28	18 to 22
Si	65 to 70	55 to 60
Fe	3 to 5	15 to 20
Al	About 1	About 1

An alloy of calcium, silicon and manganese has also been recently developed by the American concern which may prove superior, in some cases, to the simple ferros.

The Technology of the Carbon-Electrode Industry—V Baking and Baking Furnaces

A Critical Study of the Baking Process as Carried Out in Electric and Gas-Fired Furnaces—A Review of the Principles Underlying Their Construction and Design — American Operating Practice—Comparative Advantages of Different Types of Furnaces*

By Charles L. Mantell
Division of Industrial Chemical Engineering, Pratt Institute, Brooklyn

BAKING in the carbon-electrode industry has for its object the conversion of a highly resistant "green" electrode into a low-resistance finished product; the conversion of a material with qualities and properties which vary with temperature changes into one whose properties remain fairly constant over a wide range of temperatures; and lastly, the conversion of a material with low tensile strength into one which is strong and capable of withstanding hard service.

Baking accomplishes these results by a distillation-cracking action on the binder. As the temperature increases the binder successively softens, melts, loses its lighter constituents by distillation, and finally is converted into coke. At the end of the baking process, even the coke has lost whatever volatile matter it may have retained during its actual formation. According to the speed of temperature rise in the process, the volatile portions of the binder may or may not be "cracked"—that is, broken down into simpler compounds and carbon. As the result of the coking of the binder, the whole mass of the electrode is held together very strongly. Each small particle that had been covered by a film of binder is bound to the adjacent particles by an extremely thin layer of coke.

The change that has taken place during baking is easily demonstrated. A green electrode, if struck on a stone or concrete floor, causes a sound much like a thud. The same electrode after baking, if struck in the same manner, gives out a resonant bell-like tone.

The furnaces used are of two kinds, those in which the heat for baking is generated by the electric current, commonly called electric furnaces; and those in which the heat for baking is obtained from the burning of a combustible gas, commonly called gas furnaces.

Electric Baking Furnaces

The rise of electrode manufacture has paralleled that of the electrochemical industries. The electrochemical industries naturally gravitated to sources of cheap power, which were the great hydro-electric developments. Electrode plants soon located near their electrochemical customers and they themselves became users of cheap power for heating purposes. As a result, during the earlier stages of the development of carbon manufacture, the electric current was used entirely for electrode baking to the exclusion of other methods of heating. Now, however, the electric baking of amorphous carbon electrodes is becoming an obsolete procedure. Its value from the point of view of the development of the electrode industry, as well as its significance to other lines of manufacture, is believed to be sufficient to warrant its consideration in the present discussion.

The electric furnaces used for carbon baking are of the horizontal Acheson resistance type, heating the contents of the furnace by the resistance of the charge. They consist simply of two ends, which are brick walls in which the electrodes for carrying the current to the charge are supported, and two removable sidewalls of brick set up by hand without mortar or cement. The bottom of the furnace is insulated by filling it with some cheap dielectric, such as broken concrete, gravel, brickbats, etc. The appearance of the built-up furnace is that of a rectangular box. Furnaces usually are operated on single-phase alternating current at twenty-five cycles frequency with 30 to 60 volts.

The sketch in Fig. 24 shows the principal features of a standard baking furnace. Power is supplied from

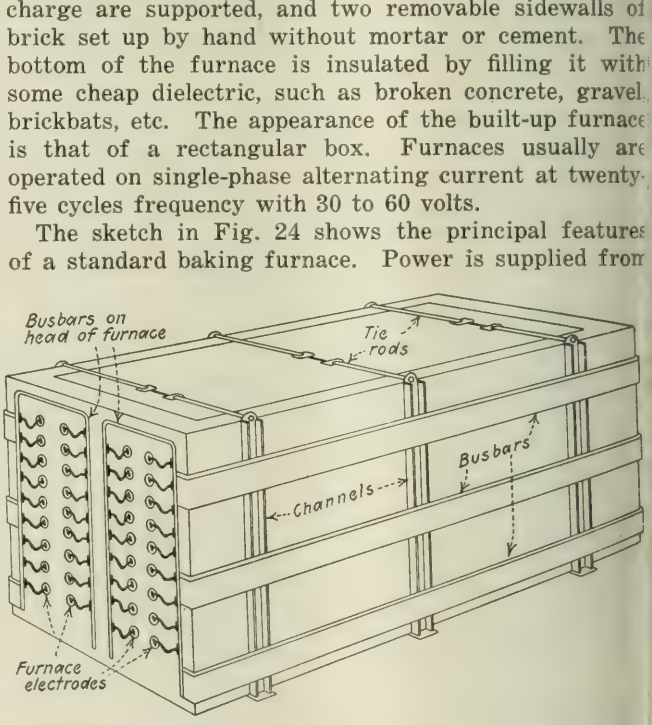


FIG. 24—SKETCH OF ELECTRIC CARBON ELECTRODE BAKING FURNACE

transformers to the furnace through copper or aluminum busbars, both heads of the furnace being connected by furnace busbars to the main set from the transformers.

Details of Construction

The sidewalls are of refractory clay brick, built in such a manner that the bricks in the wall "lock" one another in position by continuously crossing, layer after layer. Either one or both walls are torn down at the end of a run so that the baked carbons may be unloaded from the furnace. The sidewalls are held up and supported against undue pressure from the inside by channel irons placed at definite intervals. The ends of the furnaces are built of fireclay brick laid in place with mortar or cement

*The preceding articles of this series were published in *Chem. & Met. Eng.*, vol. 27, Nos. 2, 4, 5 and 6.

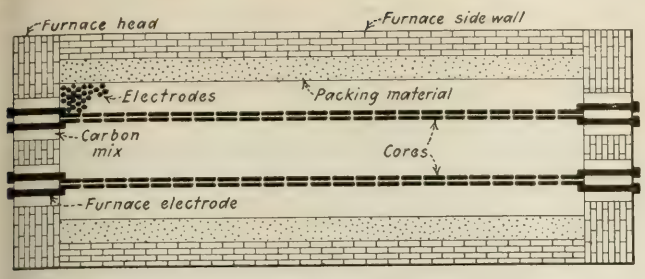

FIG. 25—PLAN OF ELECTRIC BAKING FURNACE

Transformers used are normally of the single-phase, twenty-five cycle, oil-filled type with a voltage range on the low side of 30 to 60 volts. The capacity of transformer used depends upon the size of the furnaces connected to it. Usually electrical connection is made so that four furnaces are "hooked up" to a single transformer. This is done so that the transformer may be operated at all times except when a change of connection between furnaces is being made. Switches are not provided for the furnaces, but only for the transformers. When a furnace is not "on power" (that is, not having power passing through it), the side busbars are removed so that the heads of the furnace are disconnected. Operation is such that one furnace of a group is always on power, the others are cooling, loading or unloading.

Loading the Furnace

Either one or both sidewalls have been torn down during unloading. All old packing dust is removed from the furnace. Any electrode cable, clamp or busbar replacements are made before loading is started. The furnace is opened at one or both sides so that large quantities of electrodes may be run in by trucks or handled by overhead cranes. Finely ground packing dust is then sifted between the individual carbons to fill all voids, and between the outside row and the furnace walls.

After the furnace has been completely loaded, the channel irons strengthening the sidewalls are put in place and connected with the tie rods across the top of the furnace. Just as soon as a transformer is available, the side busbars are put in place. They are supported and held in position by small arms fastened to and extending from the channels. The busbars are insulated at points of contact with the channel irons.

The Baking Process

All of the busbars of the furnace being in place, power is turned into the furnace by running the voltage regulator up to its highest point and closing the transformer circuit through the oil switch in the transformer switch room. The transformer switchboard panels are each equipped with an ammeter connected in on the primary side, a voltmeter connected to the secondary side, a power factor meter and an integrating wattmeter. Furnace log sheets are kept.

The core of the furnace, being of much lower resistance to start with, naturally takes most of the current at the beginning of the run. As a result, it heats up at a faster rate. Fig. 26 shows a comparison of the rate of heating of an average core, and the rate of heating of the temperature points. The core curve does not bear out the statement of some electric furnace men that the cores reach a temperature as high as 2,000 deg. C. during the run. The curve seems to agree with the fact that core carbons are seldom found to be graphitized, which would be the case if the core were to reach a temperature of 2,000 deg. C.

The cores, heating up at a more rapid rate, reach final temperature sooner than the rest of the furnace, which is gradually heated by radiation from the core until it conducts of its own accord. From the fact that the resistivity of the carbons just inside the core is lower than that of any other portion of the carbon pile, the indications are that this portion of the carbon pile reaches the highest temperature.

Insulation and Packing Materials

Insulation of the carbon pile depends for its effectiveness upon four things: (1) The condition of the bottom of the furnace, (2) the age of the brick sidewalls, (3) the time the sidewalls have remained intact, and (4) the width of the packing material insulating layer. The bottom becomes soaked with the pitch and tar distilling off from the binder in the electrodes during baking. With an old bottom, considerable heat will be radiated off. In this case the bottom itself ceases to act as an insulator and becomes a conductor. The brick of the sidewalls are also penetrated with tar and pitch fumes, which gradually coke inside and on the surface of the brick, thereby seriously lessening their insulating power.

It may be said that up to a certain point, the thicker the packing material layer the better the insulation.

The packing material which is principally used is pulverized calcined petroleum coke, ground in a mill of the swing hammer type, to pass a 10-mesh screen. This material has almost entirely supplanted magnesia, carborundum and fireclay, which were formerly used as packing materials. Petroleum coke does not adhere to the electrodes, making them difficult to clean, as do

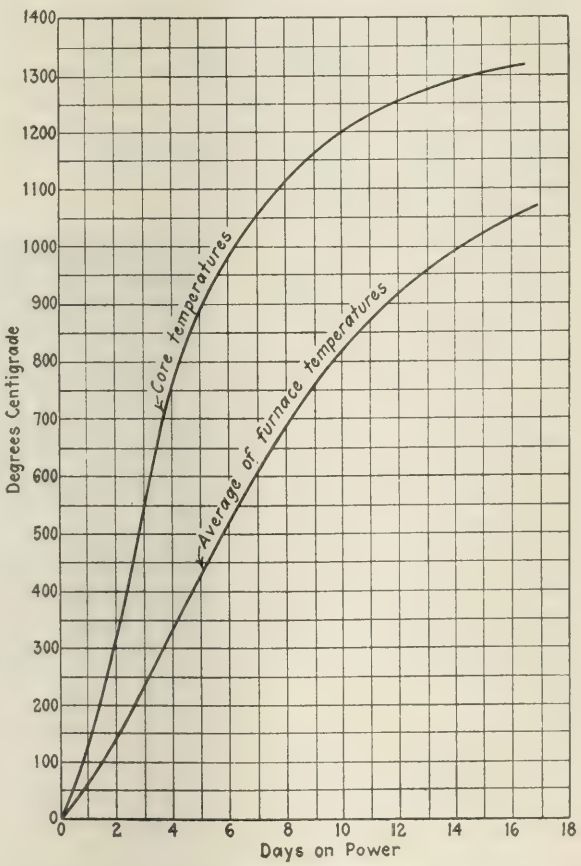

FIG. 26—COMPARISON OF CORE AND FURNACE TEMPERATURES

magnesia and carborundum. Being of the same material as the electrodes, it does not contaminate their surfaces, and furthermore is easier on the grinding mills.

During baking there is a tendency for the ash of the packing material to fuse as a result of the high temperature. Coming in contact with the sidewalls and bottoms, the packing material becomes more and more contaminated with fireclay and silica with each run. Tarry matters distilling from the electrode binder are "cracked" when they come in contact with the hot packing material on their outward passage. As a result they tend to bind together the packing material particles, and at the end of the run it is necessary to send the packing material to the grinding mills for pulverization before it can be re-used. It leaves the furnace in the form of a very friable clinker. Practically all of the packing material, save what is lost by oxidation and handling, is recovered at the end of the run.

Unloading the Furnace

As soon as the furnace has reached final temperature (1,000 to 1,100 deg. C.), the transformer circuit is opened, the side busbars of the furnace removed and placed on a furnace which is ready to go on power and the transformer circuit is closed. The furnace is then permitted to cool to a sufficiently low temperature to permit of unloading. Of course, it is understood that even if it were feasible to unload the furnace at such a high temperature, the electrodes would oxidize very rapidly and cause a large loss of material. Permitting the furnace to cool before unloading keeps the red hot carbons away from the air and prevents oxidation losses.

After the furnace has cooled, the tie rods across the top of the furnace are removed and the top layer of packing material is shoveled off. The electrodes are still appreciably hot at this time. In order to expedite the process, either one or both sidewalls are torn down. All packing dust is removed for regrinding preparatory to re-use. The electrodes are handled with the aid of tongs, for they are usually too hot to be removed by hand.

With the proper packing material, electrodes will be produced with a fairly clean surface requiring little further work on them. The most desirable baked charge is one that almost unloads itself—that is, the baked electrodes are loosened and removed with little effort. Packing dust grains larger than the No. 10 screen size are liable to sink into the carbons during the plastic stage of baking and be baked in place. This causes an extremely rough carbon to be produced, requiring much surfacing work to be done on it.

An average furnace under good operating conditions and control has approximately the following cycle: Loading (including time for making repairs if any), 2 to 4 days; on power, 12 to 20 days; cooling, 20 days; unloading 3 to 5 days; giving a minimum cycle of 37 days and a maximum of 49.

Graphitizing Furnaces

Graphitizing furnaces may be considered as modifications of the standard amorphous electrode-baking furnace. Their general construction is the same, the furnaces being about the same length, but with heads somewhat narrower and not as high. In the Acheson furnace, shown in Fig. 27, busbars, rising through the floor, are connected directly to the electrode heads, the connection being broken at these points when the furnace is off power. Loading and unloading are accomplished as with the amorphous carbon baking furnace, with the exception that a central core of larger cross-sectional area is used. Power consumption is much higher, being from 3 to 5 kw.-hr. per pound of graphitized carbon. Temperature control, being relatively difficult above 1,100 deg. C., is normally dispensed with, and the run of the furnace is regulated by power input. Packing material, sidewall and top insulation are thicker, for the furnace reaches a temperature of approximately 2,000 deg. C.

The theory of the production of graphite is that carbides are formed by reaction of the amorphous carbon and the metallic and siliceous oxides present as impurities. The furnace, however, soon reaches the temperatures at which these carbides are decomposed, distilling off the metals and metalloids, leaving graphite behind as a result of the decomposition. Packing dust used in graphitizing furnaces becomes contaminated much more readily than in amorphous baking furnaces. The packing material layers serve as a cold blanket, in which the metallic and siliceous vapors condense, re-forming carbides to some extent in the layers nearer the center of the furnace and oxidizing in the cooler outer portions. It can be seen, then, that relatively impure material may be used in the manufacture of very pure graphite electrodes inasmuch as nearly all of the contamination is volatilized.

A graphite furnace cycle is approximately as follows: Loading, 1 to 2 days; on power (depending upon capac-

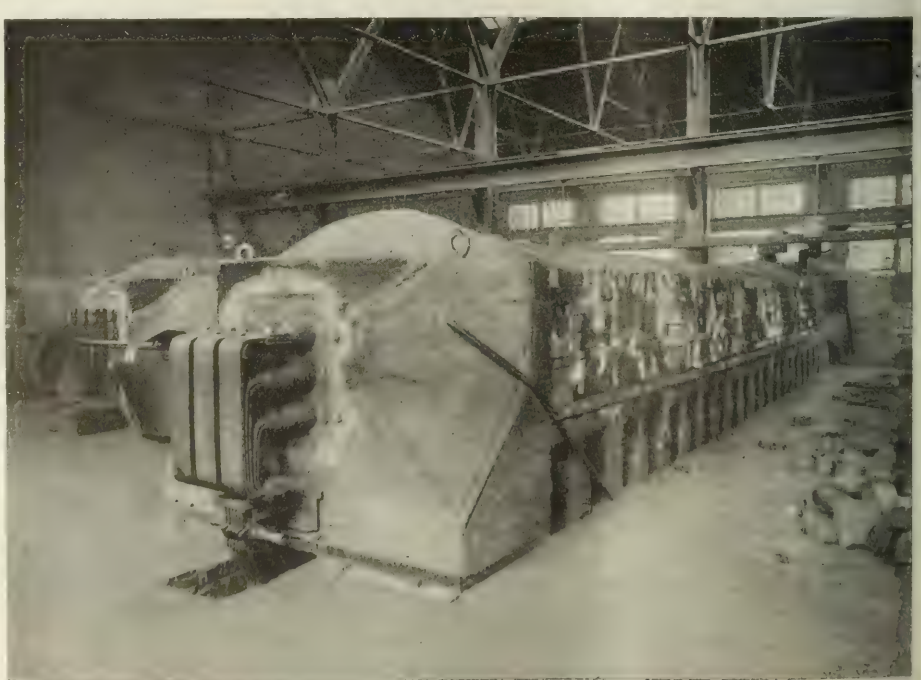

FIG. 27.—ACHESON GRAPHITIZING FURNACE

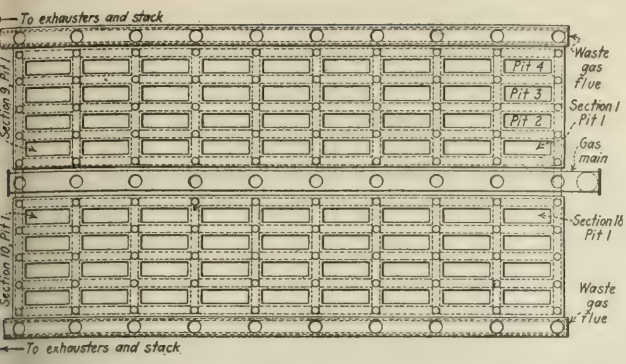

FIG. 28—PLAN OF 18-SECTION LONGITUDINAL PIT TYPE OF GAS-FIRED ELECTRODE BAKING FURNACE

ty of transformer and size of furnace), 3 to 6 days; ooling, 20 to 30 days; unloading, 1 to 2 days, giving minimum cycle of 25 and a maximum of 40 days.

Graphitized carbons are generally cleaner than amor hous electrodes when taken from the furnace; they ave fairly smooth surfaces and require relatively little urther work on them. The reason is that the tempera- ure rise is so great that the ash and vapors from the inder are distilled away from the carbons very rapidly nd are condensed in the insulating packing material ayers only and not in the packing dust between the arbons. The removal of the layers of insulating pack- ng material is more difficult than in the case of the morphous carbon furnace.

Well-graphitized electrodes have approximately one- ourth the resistivity of the corresponding amorphous arbon. Graphite carbons run from 0.00032 (Acheson, ompletely graphitized) to around 0.00080 ohm per nch cube (partly graphitized carbon, commonly called verbaked amorphous), depending upon the complete- ess of the graphitization of the amorphous carbon. he greater conversion to graphite the lower the resis- ivity.

Gas-Fired Baking Furnaces

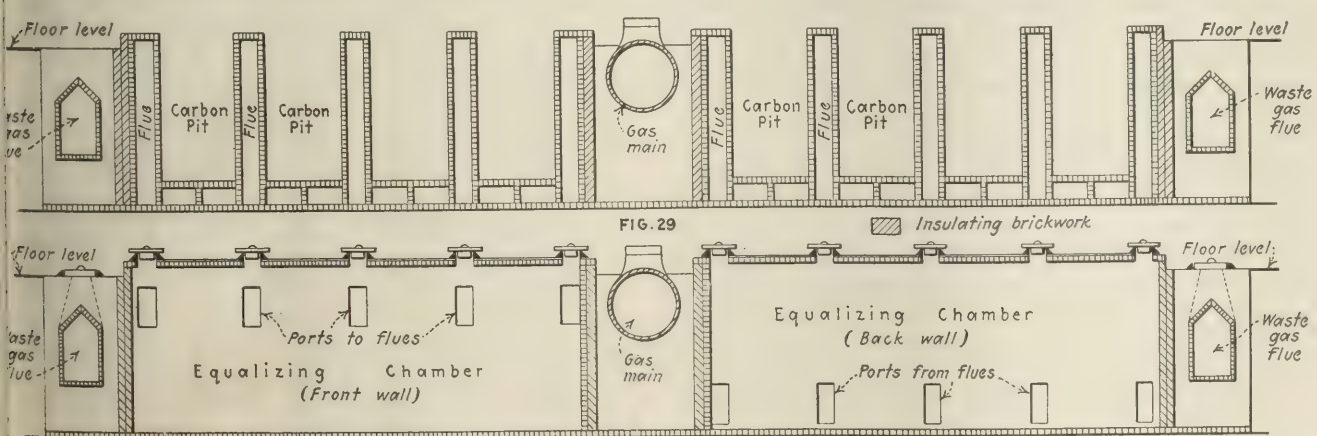
Gas-fired electrode baking furnaces are all built on he "ring" principle—that is, they are in the form of n endless chain of individual units. They are regen- rative, without having regenerators. They consist ssentially of brick chambers, in which the green elec- rodes are placed, heated by gas, burning in flues along he ends and sides, and in some cases under the bottom f the chambers.

The gas-fired furnaces may be classified in four different ways: First, in reference to the position the chambers or "pits," as they are termed, occupy in respect to each other which gives us the *longitudinal furnaces*, in which the pits are end to end, and the *latitudinal*, in which the pits are side by side. A second classification, in reference to the baffles in the flues heating the pits, gives the two classes *horizontal* and *vertical baffle furnaces*. A third, in respect to the pits, yields the *continuous* and *non-continuous pit furnaces*. The last classification is in respect to the tops of the chambers, as to whether they are covered or not. This acounts for the two classes *open-* and *closed-top furnaces*.

Construction of a Typical Furnace

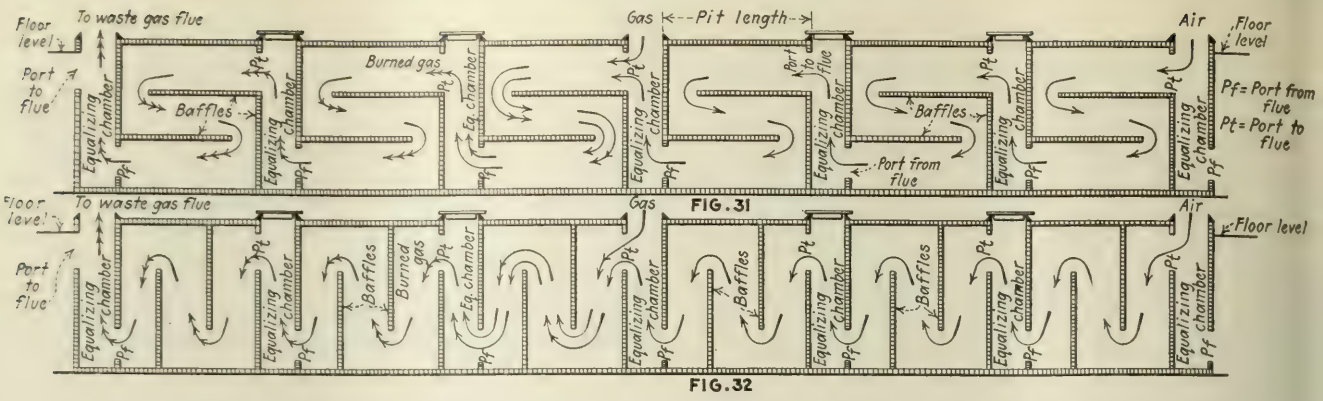
The general construction will probably be best understood in connection with the drawings of a typical furnace. Fig. 28 shows the plan of an eighteen four-pit-section, longitudinal, non-continuous pit, open-top furnace. The entire furnace forms a rectangular "ring" around the centrally located gas main. The dotted lines show the position of the flues, which are continuous for the entire furnace. The flues for the burned gases, which are usually termed waste-gas flues, are on the outside of the furnace and parallel to the gas main. Offtakes from the gas main and openings into the waste-gas flues are shown by the larger circles. Lines joining the centers of the openings in the gas and waste gas mains are parallel. Openings into the flues heating the pits are shown by the smaller circles. Connections between the gas main and flues and waste gas and flues are not permanent, but temporary and portable. When not in use, the gas-main, flues and waste-gas flue openings are closed by heavy cast-iron covers, fitting in rings or seals so that they can effectively and easily be "luted" with sand or fireclay. Fig. 29, a sectional elevation across the furnace and through the pits, affords a good conception of the relative positions of the gas-main, flues, pits and waste gas flues. The pits are separated from each other by so-called equalizing chambers with which the flues along the sides of the pits connect, as shown in Fig. 30. These chambers serve to even up pressures and volumes of gases passing through the five different channel flues.

The portion of the furnace located between two gas-main offtakes and the corresponding waste-gas flue entrances is termed a "section." Equalizing flues extend over the width of the section.



FIGS. 29 AND 30—SECTIONAL ELEVATIONS OF GAS-FIRED LONGITUDINAL PIT TYPE FURNACE

Fig. 29—Through carbon pits. Fig. 30—Through equalizing chambers, showing location of openings into chamber and ports from flues into equalizing chambers. In the rear wall the ports are below and in front above the flue level.



FIGS. 31 AND 32—SECTIONAL ELEVATIONS THROUGH MIDDLE OF FLUE SHOWING HORIZONTAL (FIG. 31) AND VERTICAL (FIG. 32) TYPES OF BAFFLES

Arrows show flow of air, gas and waste gas; P_f, port from flue; P_t, port to flue.

Gas mains are usually cylinders of steel plate lined with a highly refractive firebrick. Waste-gas flues are generally built of brick, rectangular in cross-section save for the top, which is closed over by corbelling the brick. However, no brick flue, no matter how well built, is gas tight for any considerable length of time. As a result there is a growing tendency to build waste-gas mains in a manner similar to the central gas main.

The carbon pits are formed by the brick walls of the flues, which are built of tongue-and-groove brick. The ends of the pits are tied in by the use of tongue-and-groove corner brick. All of the brickwork is laid with a refractory bond, being rubbed into place with a minimum of mortar, in order to obtain the tightest joints possible.

The reader has probably inquired of himself by this time, "Where are the gas valves?" There is a slide in the gas main at its entrance to the furnace, but this is used only when operation of the entire unit is started or stopped. There are valves of the bell or gate type in the so-called "gas elephants," which are the portable connections between the gas main and the flues.

Connection between the flue openings and the waste-gas flue is affected by the use of waste-gas elephants, built of steel plate.

In order to cause the burning gases to give up as much of their heat as possible to the section in which they are burning, baffles in the flues are used to lengthen the distance the gas must travel. Two types of baffles are employed, horizontal and vertical. Figs. 31 and 32 show sectional elevations through the middle of flues and illustrate horizontal and vertical types of baffles. In each of these the gases leave the flue of each section at the bottom, pass into the equalizing chambers, and enter the next section's flue at the top.

The Latitudinal Pit Furnace

Fig. 33 shows the plan of a latitudinal pit furnace. Flues are shown by the dotted lines. In this case the section and pit are identical. The gases advance from one section to the next by passage under the section. When baffles are used that cause the gas to pass from left to right, then right to left, and from the top to the bottom, an even number of baffles along the sides of the pit requires that there be an even number under the pit in order to bring the gases back alongside the gas main for the following section. In a like manner, an odd number of baffles along the side will call for an odd number. With vertical baffles, the gases passing up and down, and from left to right, the gases must then pass from right to left under the pit to come back alongside of the gas main for the next section. As there is but a single flue for each section, no equalizing chambers are needed.

The Isbell-Porter Co., of Newark, N. J., has patented a gas-fired latitudinal pit furnace in which it uses clay cylinder burners spaced along the bottom of the flues between the sections. Gas and air rise through these, burning in chambers above the burners. The gases rise and pass around vertical baffles set parallel to the gas main, one on each side of each burner. As a result one-half of the gases from each burner pass around the baffles on the right hand side and one-half around the baffle on the left hand side, each meeting the gases from the burners adjacent to the one they came from. Here they burn down, pass under the pit and come up through the burners of the flue of the next section.

Present practice is to build only open-top furnaces—that is, furnaces in which the tops of the pits are exposed. In the older type furnaces, covers for the tops were used made of firebrick arches held together by channels and tie rods. The arches were portable and interchangeable for any pit or section. Often the flue system was such that the gas burned over the top of the pit under the arch in addition to burning at the sides and ends. A large number of arch or covered top furnaces have outlived their usefulness, and in-

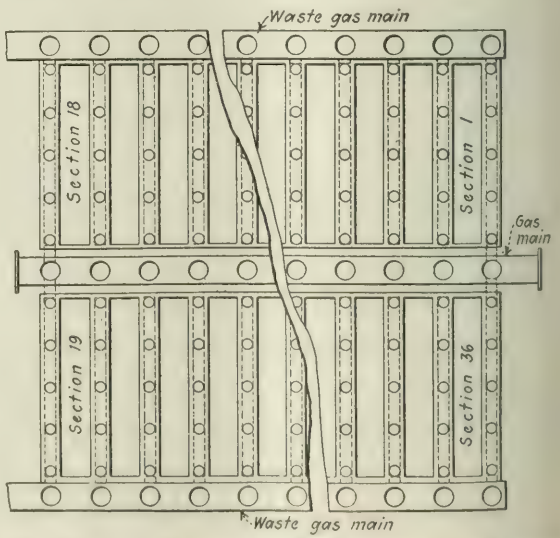


FIG. 33—PLAN OF LATITUDINAL PIT TYPE OF GAS-FIRED ELECTRODE BAKING FURNACE

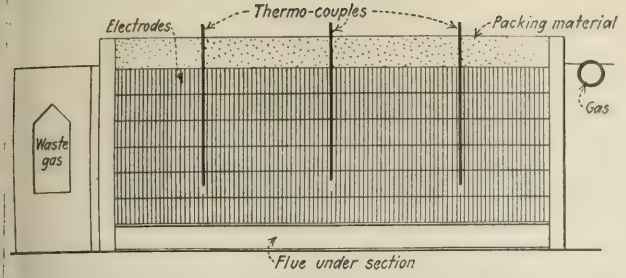

FIG. 34—ELEVATION OF SECTION OF LONGITUDINAL TYPE OF FURNACE, SHOWING LOCATION OF THERMOCOUPLES

stead of being rebuilt in the same manner, were replaced by the open-top variety.

Operation

The operation of all of the different types of gas furnaces is the same. It is always considered on the basis of an individual section in connection with its preceding and succeeding section. The cycle of operation for each section is: (1) Loading, (2) on waste gas (preliminary heating), (3) on fire (on gas) (heating), (4) on air (cooling) and (5) unloading. For an example, let us suppose that the furnace has been in operation for some time and we find a section ready for loading. It is loaded in a manner similar to the loading of an electric furnace. The carbons are placed on end as closely as possible, with packing dust sifted between them, thermocouples placed in desired positions and a covering of packing material placed over the top layer of carbons. Fig. 34 illustrates the loading of the latitudinal and longitudinal pit types.

It is to be understood that the five operations mentioned in the preceding paragraph are all going on at the same time, but in different portions of the furnace. The section now loaded is ready to go on waste gas. Operation is ordinarily so arranged that a little time allowance is made so that sections can be loaded a short time in advance.

Unloading is accomplished by "stripping" the pit—that is, removing the layer of packing material on top of the carbons. The layers of carbons at the top are "pulled" by means of short-handled tongs and the lower layers by long-handled ones. The pits are normally too hot for workmen to go down in them during unloading. After the carbons are removed and the pits have cooled considerably, the workmen enter and remove the packing dust from the bottom of the pit and any that has been baked in place and is adhering to the side and end walls of the pit.

Furnace Temperatures

Fig. 35 shows a typical curve of pit temperatures. From fourteen to eighteen cycles per year are completed per section, with an average of sixteen.

Flame temperatures are generally 200 or 300 degrees higher than the final pit temperatures, and often go as high as 1,400 deg. C. when using well-heated air and hot gas of higher B.t.u. value. Air temperatures at the point where the air meets the gas are between 500 deg. and 600 deg. C. Waste gas temperatures fall to as low as 350 deg. C. at the entrance to the waste-gas main, but are usually 100 or 200 degrees higher than this.

Spacings

In the design of baking furnaces the term "spacing" is used to refer to the number of furnace sections through which the air must pass during preheating before it meets the incoming gas. This spacing of air and gas depends upon the rate of cooling of the sections on air, the temperature required of the air for combustion and the available suction. The air temperature desired is the highest possible, as the hotter the air the hotter the flame temperature. The greater the spacing the longer will be the distance that the air passes over previously heated sections and the closer the temperature of the air will approximate that of the section next to the one on fire. The longer the air passes through a section the cooler the section will become. Usually, however, the suction available limits the number of sections through which the air can be drawn for preheating. The cycle of operations is lengthened by increased time interval of greater spacing as any given section is on air a longer time.

The spacing of the gas and waste gas is determined by the drop of the waste-gas temperature and the available suction. It is desired to bring the waste-gas temperature to as low a point as possible with a minimum loss of the sensible heat of the waste gas.

From the foregoing description it can be readily seen that any furnace is not limited to a single fire, but may have many more. In this case we must make allowance for another spacing, that of fire to fire. It

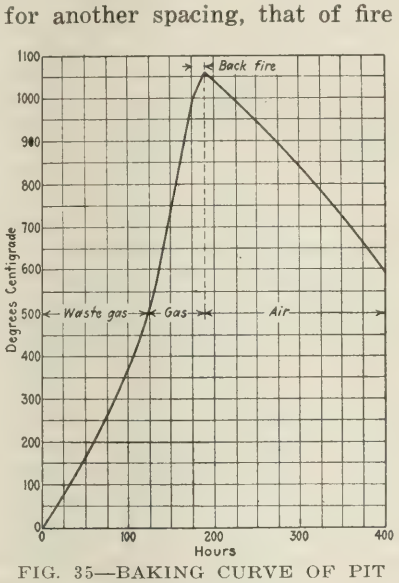

FIG. 35—BAKING CURVE OF PIT TEMPERATURES IN TYPICAL GAS-FIRED FURNACE

must be great enough to allow time for the preparatory operations, loading, unloading and repairs to take place before the cycle of one firing follows the cycle of another. The number of sections to a furnace and pits to a section is theoretically unlimited. The number of fires is fixed by the number of sections to the furnace and the spacing of the fires.

The fuel used for firing the furnace is generally raw producer gas. The producers in present practice are located as near the furnace as possible so that all of the sensible heat of the raw gas may be utilized. Producers operate on bituminous gas coal, and are of the updraft pressure type.

At first glance at a gas-fired electrode baking furnace it seems strange that only an extremely small amount of gases, from the distillation and cracking of the green carbon binder, is given off through the uncovered tops of the pits. The walls of the pits are not gas-tight and as the flues are under suction, the pits come under suction through the crevices of the walls.

As a result the vapors and tarry matters arising from the distillation-cracking action of the binder are drawn off into the flues and become a portion of the waste gas. For this reason waste gas is usually of a heavy greenish-yellow color, having a marked deleterious effect on vegetation. In the earlier stages of the industry, when electrode plants were located at places sparsely populated, this condition was not important. With increases in population, the necessity of eliminating the nuisance of the waste gas became apparent. Electrode works started to scrub waste gas and to recover, as a product of the scrubbers, a thin liquid tar.

Control

Control on the furnaces is obtained by regulation of the cross-section of the air openings, by regulation of the gas-elephant valves, and waste-gas valves or "dampers." Additional control on individual sections is obtained by regulation of the ports from and to the flues in the equalizing chambers.

A more or less unsuccessful attempt has been made to replace the electric thermocouple pyrometer in this industry by the optical pyrometer. However, the relative unreliability of the optical instrument at lower temperatures, the difficulty of training unskilled workmen in its use and the trouble in procuring black body conditions in pipes in the pits have prevented a general adoption of this instrument. The rapidity with which readings can be obtained by the use of an optical pyrometer is a strong point in its favor in the operation of the type of furnaces used in electrode manufacture.

Furnace Design

As gas-fired ring furnaces for electrode baking have not as yet been definitely standardized, their design involves a considerable amount of cut-and-try procedure. The entire field of gas baking, however, is a promising one, and the possibilities of its development are relatively great.

In general the length of the pit will have to be a multiple of the average electrode diameter. The waste-gas flue must be large enough to take care of all products of combustion, plus excess air, plus the vapors distilled and cracked from the electrode binders. Allowance must be made in designing the waste-gas flues to take care of the products of the maximum number of fires possible on each side of the furnace. The latest furnaces built have been of the longitudinal pit, vertical baffle, open-top variety. Vertical baffles, with openings through the top of the flues, permit the possibility of cleaning the flues by blowing them out with compressed air or sucking out dust, pieces of brick or mortar, etc. Horizontal baffles do not permit this.

In the design of the flues (and equalizing chambers if any) such combinations must be used as will give as intimate a mixture of the air and gas particles as possible, for the better this mixture the better will the gas be burned and the greater the heating power obtained from the gas. Having the gas and air come from opposite directions, meeting, and continuing at right angles to their previous flow, provides a good and intimate mixture.

A comparison of gas and electric baking shows that both types have low thermal efficiencies.[22] The cost of a unit of energy obtained from electrical sources i much greater than that obtained from the gasificatio of coal and the combustion of the resulting gas. A though the electric unit is ten times as large as the ga section unit, the yearly production of the electric unit i not more than one and a fourth times that of the ga unit. This is because of the greater number of cycle possible with the gas furnace. In the electric furnace there is no heat recovery of any sort, while in the ga unit the heat of the waste gas and baked electrodes ar both partly recovered.

Comparative Advantages of Gas and Electric Baking

Gas baking is gradually but surely replacing electri baking because of its cheaper cost. All of the recen installations of electrode baking furnaces, except fo graphitization, where gas baking is not a competito have been of the gas-fired variety. The greater eas and closeness of control of the gas-type furnace is decided advantage over the electric. The gas type pe mits the more or less valuable products of electrod baking to be recovered. In the electric type all sensibl heat of the finished baked electrodes is entirely los while in the gas type it is almost entirely recovere and used to give preliminary heating to the other mat rials. The maximum temperatures are much greate in the case of the electric type than in the case of th gas type, and the latter is limited by the softening poi of the furnace brickwork and the possible air tempera tures obtainable. Both types use about the same amoun of absolute energy in baking and a large part of th difference in cost may be shown to be due to the fa that a heat unit from gasified coal is much cheaper tha one from electric power. The average life of an electri furnace is about three or four times that of a ga furnace.

Finished electrodes from electric furnaces are mo difficult to clean than from gas-fired ovens, but th electric baked have the advantage of having a somewha lower resistivity. Packing dust after being used i electric furnaces is more difficult to grind and prepar for re-use than is the case with the dust from gas-fire units where fusing temperatures for the ash of th packing material has not been reached. Electric fu naces are generally very dirty, as the products of bakin burn on the outside of the furnace. Gas-fired unit on the other hand, have the baking products drawn o in the stack along with the waste gases and as a resu properly operated gas units are comparatively clean.

Editor's Note: *The concluding article of this serie which will discuss the cleaning, machining, testing an shipping of carbon electrodes, will be published in subsequent issue.*

Anti-Corrosion Association

An "Association of Manufacturers of Non-Corrodib and Anti-Corrosive Products" (a name reminiscent Dr. Herty's organization) is being organized in Englan by firms making stainless steel, acid-resisting chemic plant, anti-corrosive paints, boiler preservatives and th like. It is proposed that the association should act an Institution of Anti-Corrosion Engineers and also a Chamber of Commerce for firms making any materi or appliance connected with the prevention of corrosio It is further suggested that a public exhibition of no corrodible and anti-corrosive products should be held the near future.

[22] The heat necessary to raise the material to the required temperature (calculated from the specific heat of the material) divided by the actual heat used. See Richards, "Metallurgical Calculations."

Book Reviews

ELEKTROCHEMIE WASSERIGER LOSUNGEN (Electrochemistry of Aqueous Solutions). By *Dr. Fritz Foerster*, professor of the Institute of Technology of Dresden. Third edition, revised and enlarged. 900 pp. with 185 illustrations. Leipzig, 1922: Johann Ambrosius Barth. Series of Applied Physical Chemistry Manuals edited by Prof. Dr. G. Bredig.

The first edition of this work appeared in 1905, and the second in 1915 during the early part of the World War. The advances in electrochemistry, both theory and practice, stimulated by the demands of war were of such consequence as to make a third edition, enlarged and improved, highly desirable. In this third edition Dr. Foerster has covered a very broad field in an exceedingly comprehensive manner. The arrangement of the text follows the second edition closely, with the more recent additions to the book coming under their proper chapter headings.

An idea of the broad scope of the field of electrochemistry covered may be had from the following chapter titles, as they appear in the text: 1. Electrical energy and direct current electricity in general. 2. Faraday's law and its practical deductions. 3. Theoretical deductions from Faraday's law. The electrolytic dissociation theory. 4. Migration of ions. 5. Both voltage and energy efficiency. 6. Resistance of electrolytes. 7. Electroosmosis. 8. Production of electrical energy in galvanic elements. 9. General theories of electrolysis. 10. Electrolytic evolution of oxygen and hydrogen. 11. Special electrochemistry of metals. 12. Applications of electrochemistry to the metals. 13. Electrolytic reduction. 14. Special electrochemistry of the halogens. 15. Electrolytic oxidation.

Dr. Foerster endeavors to show the value of theoretical electrochemistry as applied to practice, and in this he is especially successful in the chapters on Faraday's law and its practical deductions, applications of electrochemistry to the metals, and special electrochemistry of the halogens.

Those interested in the electrochemistry of aqueous solutions will find this book a very up-to-date, comprehensive reference.

"AGGREGATION AND FLOW OF SOLIDS." Being the Records of an Experimental Study of the Microstructure and Physical Properties of Solids in Various States of Aggregation. By *Sir George Beilby*. London and New York, 1921: MacMillan & Co. 256 pp., 106 figures. Price $6.50.

Dr. Beilby's work is well known to chemists, physicists and metallographists. He put forth the amorphous theory of metals pertaining to the films on polished surfaces and amorphous metal generated at slip planes by plastic deformation. The present book deals not only with metals but with all solids, and is in eleven sections.

The section on the microscope is interesting, because in it is illustrated how the microscope can be utilized to determine the type of surface on a solid. Dr. Beilby devised a method of observing very small particles some years before the ultra microscope was described.

In the section on surface tension a number of experiments are described on the character of oil films and of thin metal leaves. When a water surface is touched with a needle which has been dipped in an oily liquid there occurs a definite sequence of changes in the state of aggregation. A continuous film first forms over the surface in all directions. Two forces are present, one which tends to keep the oil in the form of a continuous film and the other which tends to reduce the surface area of the oil and hence to change it into spheres. The spreading continues until the film becomes so thin that the surface tension force of the oil dominates the attractive force between water and oil. The surface then becomes punctured all over with small round holes, which increase in size. At the beginning of the change the oil network is continuous, but the process of gradual change produces a form in which the water surface becomes continuous and the oil concentrated in isolated drops. The state of equilibrium of each drop depends on the surface tension of the oil and the attractive forces between water and oil at the contact. Similar changes take place in thin metal leaves; for instance, if a leaf of continuous gold is mounted on glass and heated to 400 deg., the continuity of the gold completely disappears, and the isolated portions of gold become thicker than the original leaf, due to the forces of surface tension. "The foregoing illustrations show that an increase in the mobility of the molecules of a solid, which is still far short of the freedom of the liquid state, is sufficient to enable the force of surface tension to assemble the molecules of a thin film into new forms of aggregation."

In Section III the author gives the outstanding characteristic of a solid as "rigidity," which implies the retention by the molecules of fixed positions relative to each other so that energy has to be expended to change these fixed relations. A number of types of aggregation are considered. Atoms or an aggregation of atoms forming molecules may be arranged in definite and repeating patterns to form crystals. Such crystals may be perfectly dense or, under certain conditions, may exist in an open formation.

Particularly interesting is the formation of calcium carbonate. Carbon dioxide from the air first forms a thin film of calcium carbonate on a drop of lime water. With the continued addition of CO_2, the film breaks up into particles (which the author calls "spicules") of such small size as to move about with Brownian movement. "If two spicules have an encounter, they at once coalesce and the enlarged unit proceeds to fresh encounters till its mass becomes so large that it sinks to the bottom as a granule and rests there. Its power of absorbing other spicules having increased with its mass, it now acts as a center of attraction to the still active spicules which play around it with swift to and fro movements, ultimately darting into it and being absorbed. By focusing on the bottom of the cell the granules were seen to grow till they took the outward form of rhombs."

Open formation in metals may be caused by exposing them red hot to ammonia. The general effect is a slight increase in weight with a continuous change in structure—holes are developed, increasing the volume enormously. "Rolls of fine wire gauze of copper were heated in a porcelain tube at 800 deg., and a current of ammonia was passed through for 70 minutes. It became so brittle it could not be bent without breaking. Its color was bright pink, and its surface was so completely disintegrated that metallic luster had disappeared. Under the microscope the bubble structure was very obvious. The diameter of the wires had increased two or three times."

Perhaps the author is best known for his work on polish and surface condition of solids. In Section V two fundamental principles of polish are put forth: 1. In every substance sufficiently homogeneous to be polished at all, the fundamental principles on which polishing depends are absolutely identical. 2. The polished surface on a solid substance is as truly due to the presence of a surface tension skin as is the surface of a liquid.

Evidence is given to substantiate these principles. The author holds that amorphous substances like glass have liquid surface tension skins on their cold surfaces, different from the structure at a fracture. The latter surface can be polished cold so as to produce a surface tension skin; in fact, the resistance to polish on a broken surface of glass is much less than on one already polished or one cooled from a high temperature. When a surface of a crystal is polished a surface tension skin many molecules thick is formed. This skin is vitreous-amorphous in character. The surface of calcite crystals can be scratched and these can be completely covered by polish, yet caused to reappear by proper etching.

A sharp distinction is made between grinding and polishing. It was formerly believed that polishing was only very fine grinding and that grinding was the cutting away of a substance by the hard particles of the abrasive. The author shares the old view as regards grinding, but puts forth the hypothesis that polish is the result of surface flow caused by the gripping of the surface molecules by the particles of the polishing powder.

Some interesting experiments are described on the formation of similarly oriented crystals of sodium nitrate.

These crystals permitted to form either on a cleavage plane or polished surface (parallel to a cleavage plane) were oriented similarly, showing that the crystallic attraction of the calcite extended through the supposedly vitreous-amorphous polish film. Realizing that this experiment might cast doubt on the existence of a vitreous film, the author deposited isotropic films of calcium carbonate and oxalate on a polished surface of calcite and then permitted the sodium nitrate crystals to form. Up to a certain thickness of deposited film (many molecules thick) the sodium nitrate showed the parallel growth, but beyond that a perfectly random arrangement.

Sections VI and VII deal with the generation of amorphous metal at the slip planes by plastic deformation of ductile metals. The mechanical properties of metals are considered from the viewpoint of the amorphous theory. The treatment is substantially the same as in the author's May lecture (1911) before the Institute of Metals, and discussed at length by the reviewer in *Chemical & Metallurgical Engineering* for Oct. 12, 1921 (vol. 25, p. 697). It is postulated that plastic deformation produces vitreous-amorphous metal at the slip planes; the amorphous metal is hard and hence the hardening by cold work. The amorphous metal is mechanically stable because of the relatively low temperature. When a cold-worked metal is heated the amorphous metal recrystallizes, restoring softness.

It is the author's opinion that flow by slip takes place in rocks and in ice under conditions of great and unequal pressure, rather than softening by the lowering of the melting point. An ice column nearly 60,000 ft. thick would produce only enough pressure to effect melting at a temperature of —12 deg. C. Therefore, plastic flow and recrystallization seem necessary to account for the flow in glaciers.

In Section IX a tentative hypothesis of molecular "pulsation cells" is offered. "The molecule, which for simplicity we shall take to be monatomic and spherical, is elastic and is capable of responding to ether-borne vibrations by vibrations of a period proper to itself and of an amplitude proper to the temperature attained. Its elasticity may be either of form or of volume; again for simplicity's sake, let us assume the elasticity to be that of volume. The vibration of the spherical molecule will be spherical pulses. The effect of these pulses, the period of which is necessarily rapid, will be to surround the sphere with a 'pulsation cell' the thickness of which will depend on the amplitude of the pulsations. The amplitude of the pulsations will in its turn depend on the temperature, so that for each temperature the cell will be of definite thickness.

"When an aggregate of spheres at the absolute zero is energized by heat, each molecule as it becomes energized will surround itself with a pulsation cell proper to the temperature which it has reached, and the molecules will be pushed apart to a corresponding distance."

In 1857 Faraday gave the Bakerian lecture entitled "The Experimental Relations of Gold and Other Metals to Light." Phenomena of the color of light transmitted through thin gold leaves were described but not explained. In Section X Beilby offers an explanation of these phenomena which he believes agrees with all of the experimental observations. The key to the interpretation is the decrease in density of thin films of metal on mild heating. The particles arrange themselves in "open formation" as the first step in the change in state of aggregation under the influence of surface tension forces. The open formation accounts for the observed decrease in density, enormously reduced electrical conductivity, the optical phenomena and sponginess as shown by the absorption of water and other liquids.

The book contains 106 illustrations, many of which are highly magnified micrographs, a collection which is unique in individuality and variety. A number of excellent colored illustrations are reproduced.

Although the experiments were made during the last 20 years, the author states in the preface that the conclusions are based on mature consideration just prior to publication. Besides containing accounts of many interesting and varied experiments the book is a fine piece of scientific literature.

The greatest value of the book, in the opinion of the reviewer, lies in the experimental methods described. The author combines almost infinite pains in performing with rare ability in planning his experiments; their boldness and originality are equaled only by their simplicity. The author's appreciation of important variables and his skill in controlling them entitles him to a place among the foremost experimenters. It is a pleasure to acknowledge the great indebtedness of metallographic science to the work of Dr. George T. Beilby.

ZAY JEFFRIES.

METALLOGRAPHIE. By *W. Guertler.* Vol. II, Part I, Section 3: Elektrochemische Metallkunde, by *Dr. R. Kremann.* Berlin, 1921: Borntraeger.

Dr. Guertler writes in his preface to this volume that the enormous expansion of scientific knowledge in the field of metals and alloys, in addition to certain unfavorable circumstances growing out of the war, have made it impossible to carry out his original plan of completing the handbook under his own authorship. The present volume is accordingly the work of a collaborator, Dr. Kremann. One finds no difficulty in understanding this change of purpose when it is recalled that several thousand pages of the handbook have already appeared. This undertaking is evidently planned with the intention of assembling under one title in a series of volumes everything pertaining to theory and practice within the metal industries no matter how expansive the effort becomes or how long it may require for completion. Those of us who work in this field should therefore receive these contributions with extreme satisfaction, feeling grateful that so much is being done to chart the progress in a field of growing complexity.

The volume in hand constitutes the third section of the first part of the second volume of the handbook and comprises about 650 pages under the sub-title, "Electrochemical Science of Metals." It is essentially a critical review of published investigations describing the change of potential with concentration in binary alloy systems. Five ternary systems are also included. The literature is treated from the constitutional standpoint and the relations between electrochemical potential and various established types of constitution are set forth in detail. Those who desire to consult the work of individual authors quoted in this volume will run into difficulty, inasmuch as, in harmony with the practice in earlier volumes, no direct references are given. The reader must be content with the bare knowledge and date of authorship until, at the end of the entire undertaking, a table listing the literature appears.

About thirty pages of the book are occupied by introductory statements of theory and methods of potential measurements, including a six-page discussion of passivity.

Following the treatment of binary alloy systems, some attention is paid to the subject of alloying by electrochemical methods. The author's discussion of the use of potential-concentration curves of binary alloy systems as a means of determining the alloy compositions resulting from ordinary electrolytic precipitation reactions should be of especial interest to those generally engaged in alloy investigations. Qualitative or semi-qualitative data defining the character of precipitate produced in many reactions of this sort are included. Thus we read on page 444 that the lead precipitated by cadmium from dilute solutions of lead salts is practically pure and on page 451 that tellurium precipitates a compound of the formula Ag_2Te from silver nitrate solutions. As very little of the data on this general subject is of recent origin it should be used with caution.

The subject of electrolysis, mainly from the standpoint of alloy formation at the cathode, is handled elaborately with reference to a large amount of well chosen data. Important combinations of metals such as Cu:Zn, Cu:Sn, Cu:Ni:Zn and amalgams are discussed.

Other important topics included are the electrolysis of molten salts, anodic behavior of metals and alloys and finally a brief chapter on electrolytic refining of metals.

This volume probably makes use of the largest collection of references relating to the electrochemical properties of metals thus far assembled. It is unfortunate that these references are abbreviated so as to be virtually useless in their present form.

C. H. MATHEWSON.

Synopsis of Recent Chemical & Metallurgical Literature

Internal Stress in Brass Tubes

A method of studying the effect of w-temperatrue reheating on the relief internal stress in metal is used by oore and Beckinsale[1]. If a flat strip metal t inches thick is bent to a dius r, the stress in the outer fiber f below the elastic limit) is equal to $t \div 2r$, where E is Young's modulus. ow while held in this shape, a heat-eatment is given it, after which the rip is released. It will assume a form mewhere between the straight line id an arc radius r, and from the re-ilting curvature the stress relieved iring heat-treatment can be com-ited.

Internal stresses rapidly fall during ie first few minutes of low-temperature nneals, the faster the higher the tem-erature. Thereafter, further relief ecomes slower, almost vanishingly nall. However, internal stresses in ard drawn condenser tubes as high as 3,500 lb. per sq.in. are reduced to 2,000 lb. after 60 minutes at 250 deg. ., a heat-treatment which also im-roves their physical properties with-it softening the metal, as shown by ie following results:

	Original Tube	Annealed 60 Min. at 250 Deg. C.
rinell hardness	164	163
roportional limit	27,000	45,000
ield point (extension 0.2 per cent)	71,200	77,600
ltimate strength	85,000	83,300
longation	11	17
eduction in area	28	51

It has already been found that season-racking probably requires internal tresses of 20,000 lb. per sq.in.; cer-ainly it is very improbable if they are educed to 10,000 or 11,000 lb. per sq.in. ven when submitted to ammonia imes. Pushing the heat-treatment to 00 deg. C. even for 10 minutes will educe ordinary internal stress to be-ow the lower figures, and cause almost qual improvement in the physical prop-rties noted in the above table. Most everely stressed tubes would require 0 minutes at 300 deg. C.

Bengough and Hudson[2] recommend a 0-minute oxidizing heat at 280 deg. C. or aid in resisting corrosion. It is ow seen that such a heat would like-ise be a sure preventive against sea-on-cracking and splitting from internal tresses.

Utilization of Iron Ores Containing Vanadium

Iron ores containing low percentages f vanadium have not yet been used for he production of V with the exception f some converter slags, emanating rom certain Minette ores. Attention as been given to bituminous sub-tances containing vanadium, even though sparingly, because these materials give a high-grade product simply through burning.

Swedish magnetic iron ores containing appreciable amounts of V also generally contain titanium in considerable quantities as ilmenite, according to Björn P. F. Kjellberg, state inspector of mines, Sweden, (*Jornkontorets Annaler*, 1921, p. 147). Magnetite appears to hold the vanadium, but the minerals as a rule occur in such a manner that even after the ore has been finely ground they cannot be completely separated, and it is generally impossible to produce a concentrate containing more than 50 to 55 per cent of iron, up to 1.5 per cent V, and 5 to 15 per cent Ti. A remarkable advantage of these Swedish ores is that they generally are very low in phosphorus.

Rich concentrates having the lowest possible percentage of Ti may be smelted with charcoal in an electric pig-iron furnace, slagging both the V and Ti. The slag consequently contains a considerably higher percentage of these metals than the raw material. It is then given a roast with salt and iron sulphide, and leached with hot water. Vanadium in solution is precipitated as iron vanadate by ferrous sulphate, filtered and washed. After drying it contains 50 to 55 per cent vanadic oxide (V_2O_5).

Another possible method of refining the slag is to smelt it with niter cake and coal, and leach out the sodium-vanadium sulphide with hot water. Excess acid precipitates the V as sulphide, which after calcination becomes V_2O_5.

Low-vanadium, high-titanium concentrates can be turned into color material (red ocher) and vanadium extracted at the same time. The fine-ground dry material is stirred into sulphuric acid and the pulp heated gently under intermittent stirring until the metals are converted into sulphate. This is heated to a comparatively low temperature to drive off the sulphuric acid, which transforms the Fe and Ti into insoluble oxides, a pigment of fine color and superior qualities. Soluble V compounds are extracted by a hot solution of caustic soda, precipitated as vanadium sulphide and calcined.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Zirconia Refractory — By adding a limited quantity of steatite to zirconia and then heating the mixture, a new compound is formed that makes an excellent refractory material for many purposes if the steatite is not less than 15 per cent nor greater than 40 per cent. When the steatite is much less than 15 per cent, the compound lacks strength and uniformity, while if in excess of 40 per cent its fusing point will be too low. The best results are produced when the compound is formed from 80 per cent zirconia and 20 per cent steatite, the resulting material having great physical strength over a wide range of temperatures and having a fusing point but little lower than zirconia, thereby filling all the requirements of a high refractory material.

In making the refractory material, the zirconia and steatite are separately finely ground and then thoroughly mixed in definite proportions by weight. Water is then added in sufficient quantity to enable the mixture to be pressed into bricks, which are thoroughly air dried. After drying, the bricks are fired in an electric or other suitable furnace until they are fused. The fused compound is then cooled, preferably in water, and thereafter ground to such a degree of fineness that the particles will pass through a 30-mesh or finer screen. The object in fusing the mixture is to produce a uniform compound that will not shrink after being molded into final form, the zirconia and soapstone shrinking to a considerable extent when first heated.

The finely ground compound is then mixed with a small percentage of volatile binder, preferably 1½ per cent of gum arabic and a very small quantity of water, and pressed under high pressure into final shape as bricks, crucibles, insulators and the like. They are then fired at a temperature that will completely volatilize and drive off the binder and soften but not fuse the compound. The resulting articles after cooling are hard, dense and smooth and of their original shape and size, there having been no warping or shrinking during the firing.

Among the many advantages of the new refractory material are its high melting point, its great strength at all temperatures up to its softening point, its ability to withstand the cutting action of molten metal, the capability of making a refractory material of varying strength and heat resistance by varying the proportions of the ingredients to meet any requirements. (1,418,372; Charles A. French, assignor to International Harvester Co. June 6, 1922.)

Mold for Hot-Top Ingots—S. E. Hitt of Elyria, Ohio, and J. I. Peyton of Chicago, Ill., propose an ingot mold whose topmost part is hollow cast. A vacuum is maintained in this space and it is claimed that by this means the top part of the solidifying ingot will remain liquid much longer than the lower, thus acting as a sink-head to fill any pipe or contraction cavity which may be formed. A hollow-cast top may also be bolted to the top of an ordinary mold. Various precautions are mentioned concerning the manufacture of the mold, its design and the maintenance of the proper vacuum. (1,422,572; July 11, 1922.)

SO_2 From Smelter Smoke—G. C. Howard of Tacoma, Wash., patents certain improvements in the process of recovering SO_2 from dilute mixtures, such as smelter smoke. He delivers cooled smoke to the bottom of an open

"enriching" tower, passing upward through sprays of SO_2 solution. From this tower the smoke then goes through a packed absorption tower. A water current in closed circuit is circulated in a contrary direction through both these towers, sufficient being drawn off to supply the gas plant. Here part of the solution passes through a heat interchanger and thence to a boiler, where the SO_2 is driven off. This gas passes to a cooling tower, where it is cooled by the remainder of the solution from the absorption plant. Thence the cool gas is dried in a scrubber through which H_2SO_4 is circulated, when it is ready for liquefaction. Warmed solution from the cooling tower just mentioned passes to the boiler either direct or through the heat interchanger at the entrance of the gas plant. Spent liquor emerging cool from the heat interchanger is returned to the enriching tower. Thus the operation requires a minimum of make-up water and a minimum amount of heat. (1,417,066 and 67; assigned to American Smelting & Refining Co.; May 23, 1922.)

Electric Smelting Furnaces for Zinc—Filip Tharaldsen, of Trondhjem, Norway, patents such a furnace which is essentially a smelting chamber inclosing an arc. Charging is effected through a tall shaft, whereby much volatile matter is driven from the raw materials before it enters the smelting chamber. Zinc vapor is conducted to a series of inclined condensers, each one air-jacketed to absorb the heat from liquefaction and to regenerate the temperature. Slags are drawn from the furnace periodically, and further treated, if their zinc content warrants. (1,417,953; May 30, 1922.)

Manufacture of Butyric Aldehyde—According to British patent 166,249, which has recently been taken out in this country, butyric aldehyde is prepared by passing normal primary butyl alcohol in a vapor state over a fused cupric oxide catalyst. The temperature of the catalyst and vapor is maintained at between 200 and 350 deg. C., although the preferable temperature range is between 280 and 320 deg. The vapors pass through a condenser, and are there separated from hydrogen. The resultant butyric aldehyde may be separated from the unchanged butyl alcohol by distillation, and the latter returned to the catalyzers.

A particularly high percentage conversion is claimed for this process. Thus, in a ¾-in. copper tube packed for 26 in. of its length with fused cupric oxide it is possible, while working at 300 deg. C., to pass through 240 c.c. per hour of normal butyl alcohol, and obtain 75 per cent conversion in one passage. (1,418,448; David A. Legg, assignor to Matthews Atkinson Adam; June 6, 1922.)

Separation of Petroleum-Oil Sludges—Sterling H. Diggs, assignor to the Standard Oil Co. of Indiana, has been granted a patent for the treatment of the acid sludge such as is normally obtained in the manufacture of lubricants from petroleum oil. The method consists of treating this sludge with an intimate mixture of water and the sludge sulphonic acids of the character usually derived from the fuming-acid treatment of mineral oil. The fuming-acid sludge referred to is produced by the action of relatively large quantities of fuming sulphuric acid from heavy petroleum oil of the character used for medicinal purposes. Prior to the mixing, the fuming-acid sludge has usually had the bulk of its sulphuric acid separated from it. This may be readily accomplished by the addition of water to the sludge, followed by the thorough boiling of the mixture and settling.

The mixture of oil sludge, fuming-acid sludge, gas oil and water or weak acid having been made, this is now steamed until it is nearly at boiling temperature. The sulphuric acid contained in the sludge separates out at the bottom of the tank in a form of about 30 deg. Bé. acid. This is drawn off, more water or weak acid added, and the mixture again steamed, after which a second stratification takes place. The process may be repeated until the gravity of the acid recovered is from 8 to 10 deg. Bé., beyond which stage it is unnecessary or unprofitable to carry the concentration. (1,418,781; June 6, 1922.)

Preparing Size for Paper Making—The resin size ordinarily used in the manufacture of paper is a mixture of resin soap with varying amounts of free resin. In dissolving such a mixture, the resin soap acts as an emulsifying agent for the free resin, and it is evident that the facility with which emulsification will take place must decrease with an increase in the proportion of free resin. The ordinary size used by paper makers contains about 25 per cent of free resin, but it is often desirable to use proportions of free resin amounting to about 45 per cent of the total resin.

Dr. Oliver Kamm, assignor to the American Writing Paper Co., of Holyoke, Mass., has patented a method which consists in heating the size with an exactly sufficient quantity of water to form a clear emulsion of size-in-water at a given temperature and in diluting this emulsion by pouring it into a large volume of water. The preferred temperature for the preparation of the first concentrated emulsion is the boiling point of the solution. Cold water may be used for the subsequent dilution.

In preparing dilute resin emulsion containing 30 per cent of free resin, one part of F grade resin is treated with one part of water containing sufficient quantity of sodium hydroxide in water to convert 70 per cent of the resin into resin soap. This mixture is heated until a clear homogeneous solution is obtained. Four to five parts of hot water are then added and the mixture heated practically to the boiling temperature until a clear homogeneous solution is again obtained. The actual quantity of water to be added is dependent to some extent upon the particular grade of resin used. This clear emulsion is then diluted by pouring it into 45 parts of water, thus producing a diluted solution containing approximately 2 per cent of total resin. (1,415,363; May 9, 1922.)

Paint Pigment—LeRoy Baker of St. Louis, Mo., has received a patent for the production of a sunproof zinc white pigment, the particles of which are claimed to be of uniform size and of microcrystalline formation. A solution of zinc sulphate is heated with steam and subjected to air under pressure. At the same time a solution of a metallic peroxide, such as calcium or barium peroxide, is added in the proportion of about 1 per cent by weight of the zinc present. The hydrated zinc oxide thus formed is filter-pressed and mixed with a solution of barium sulphide. The precipitated pigment is dried and calcined. It is then reground while wet, again washed, filter-pressed and finally dried and packed for the market. The inventor claims that the properties of this pigment are the result of the precipitation from basic solutions. Reference is also made to application filed July 16, 1919, Serial No. 311,296. (1,413,565; April 25, 1922.)

Recovery of Volatile Solvents—A number of interesting improvements have been outlined by G. W. Coggeshall and T. M. Rector in their recently patented process for the recovery of volatile solvents such as alcohol and the like from material in or with which they have been used in the coating of fabrics. The general process with which these investigators worked consisted in passing a current of gas such as air over the coating material, the gas being warmed to a temperature sufficient to volatilize the solvent. The mixture of gas and solvent vapor is then brought into contact with a suitable adsorbent such as charcoal or activated carbon. The volatile vapors are adsorbed by the material and the mass is then heated to volatilize the solvent which may be recovered by condensation. A method is outlined for reducing the volume of fresh air needed, thereby increasing the concentration of solvent vapor in the air-vapor mixture passing to the adsorbers. It has also been shown that if a slow current of air or of a gas of greater molecular weight is passed through the adsorber during the heating of the adsorbent mass to drive off the vaporizable solvent and this incondensible gas is passed along with the condensible vapor through the condenser, a larger percentage of vaporized solvent is removed from the mass of the adsorbent in the same length of time than when no incondensible gas is so used. It has been found to be advantageous to remove such gas from the condenser or collecting vessel, reheat it and again pass it through the heated adsorbent material. (1,418,363; assigned to the Institute of Industrial Research, Inc. of Washington, D. C., June 6, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Potash Bounty Defeated in Senate

Party Lines Swept Aside in Vote of 32 to 30 Against Subsidy Proposal—Small Chance Now of Saving Potash From Free List

THE PROPOSAL of the Senate Finance Committee to substitute a ounty for the protective duties pre-iously prescribed for potash was re-ected by the Senate on Aug. 8 by a ote of 30 to 32. The vote was taken committee of the whole. The first tep was to reject the original pro-osal of the Finance Committee pro-iding various rates of duty upon the nportation of potash. This was done y a vote of 66 to 1, the single objec-on being registered by Senator Short-idge, who apparently was willing to t well enough alone. The next ac-on, therefore, was to subject potash the bounty provision, and that fail-ig it was left upon the free list. An pportunity will be afforded to bring ie matter up again when the bill is onsidered in the Senate proper, but is thought that the chance is slight f saving potash from the free list.

Would Foster Industry

During the discussion of the item it as admitted frankly that the bounty as substituted for the duty when it ecame apparent that the duties pro-osed would be voted down. Senator IcCumber, chairman of the Finance ommittee, in urging the adoption of ie bounty proposition pointed out the nportance of having a domestic potash idustry to curb the monopolistic con-ol of the other sources of supply. He nphasized its importance in both eace and war and expressed the opin-n that the $9,500,000 would prove to e a very good investment for the eople of the United States.

"The committee was faced with this tuation," he told his colleagues. "If e raised the duty on potash undoubt-lly it will be carried on to the con-mer, but while the consumer is pay-ig this added burden for a few years, do not say how many, which under ie provisions of the bill as introduced as carried only for 5 years, we would e developing an industry in the United tates which would operate as a lever t least to preserve our own prices to me extent and to protect them gainst the possibility in another war f increasing from $40 to $100 per n."

German-Alsatian Combine

Senator Smoot of Utah laid before ie Senate the contracts which Ameri-an purchasers were compelled to sign order to secure German and French potash. The contracts show that Germany and France have agreed on this form of contract and have decided to permit Germany to take 75 per cent of all American orders, while the French producers are to fill the remaining 25 per cent. This led Senator Reed to remark that France and Germany have no difficulty in getting together when it is a case of "skinning" America in a commercial transaction.

Lenroot Leads Opposition

The committee failed to explain to the satisfaction of the Senate why the bounty policy, if applied to potash, should not be applied to manganese, tungsten and other products of which the domestic production can supply at best only a small percentage of the country's requirements.

Senator Lenroot of Wisconsin expressed the hope that the Senate would not "embark upon the sea of bounties." "If it does," he said, "and the door be opened, as is proposed by the committee, the Treasury of the United States will have to be enlarged, because there will be demands for bounties from every quarter. If the precedent be set here today, we will have in the future pork-barrel bills composed of bounties compared to which river and harbor bills will seem as nothing. I am amazed that this committee, which has under its care the protection of the Treasury of the United States, should bring to the Senate such a proposition as this."

"If the farmer is not sufficiently interested, why does the chairman think the people of the United States as a whole are willing to do what the farmer himself is not willing to do?" he inquired.

Nebraska Deposits Sufficient for Only 10 Years

The Wisconsin Senator quoted from the Tariff Commission's report to show that the Nebraska deposits will be exhausted in 10 years. He said Nebraska would absorb 50 per cent of the bounty for an industry that would have to go out of business anyway in 10 years. He suggested that it would be better insurance for another war not to exhaust the Nebraska potash. Outside of Nebraska, he said, the $9,500,000 would go to three or four companies only. In addition to the question of policy, he pointed to opinions of the Supreme Court which he interprets as an indication that a bounty is unconstitutional.

Bounty as Aid to Agriculture

Senator Smoot, supporting the bounty, urged the Senate to free American agriculture from the clutches of two powerful syndicates, one in Germany and the other in France, "both working in complete harmony in the control of the potash of the world." He said the German potash syndicate is back of the propaganda designed to influence American farmers against the use of American potash.

Senator Reed said that it is intolerable that American concerns be permitted to sign such contracts with foreign producers. "That is a trust practice in its worst form," said the Missouri Senator. "My judgment is that any American manufacturer who will do it ought to be sent to jail for a long term."

Senator Simmons of North Carolina predicted that with so large a bounty enough potash would be made to require the payment of many times $9,500,000. "At the end of 5 years," he asserted, "if that bounty be withdrawn, the industry will go to pieces in the face of this same foreign competition. It is impossible for us to make in the United States by expensive processes a potash that can be sold in competition with the potash that is found abroad in inexhaustible quantities and needs only to be dug up, as we would dig up sand."

Arsenic Goes on Free List as Essential to Boll Weevil Control

White arsenic and arsenious acid were put on the tariff bill's free list on Aug. 8 when the Senate, by a vote of 29 to 25, struck out the amendment of the Finance Committee, proposing to make each commodity dutiable at the rate of 2 cents per pound. The amendment, which overrode the Finance Committee, was offered by Senator Smith of South Carolina. His principal argument in support of his amendment was that arsenic is the basis of insect control and is essential to agriculture. He presented a report from an agent of the Department of Agriculture in which it was stated that great difficulty is being experienced in securing calcium arsenate.

American Peat Society Plans Annual Meeting

The American Peat Society will hold its sixteenth annual convention at South Bend, Ind., Aug. 29 to 31. The activities of this society are devoted to the diffusion of knowledge concerning the farming of peat and muck and it is made up of men from all parts of the United States and Canada.

The program will extend over 3 days and will cover many phases of intensive agriculture and peat and muck utilization. Papers illustrated by lantern slides of interest to intelligent practical farmers and persons concerned with fuel will be presented by representatives of the Departments of Agriculture, Commerce and Interior, by representatives of state agricultural and geological institutions and by private professional and business men. Excursions will be made to experimental plants near South Bend.

There are 12,000 square miles of muck and peat land in the Great Lake and New England States that can be used for the production of truck and general farm crops, fertilizer and fuel. Fourteen billion tons of fertilizer or fuel is available. The fertilizer is worth $10 per ton and the fuel can be produced for $1.50. In some parts of the country the proceeds from the cultivation of muck soils amount to over $500 per acre per year.

Among the papers to be presented are the following:

"Peat Resources of the United States," by C. C. Osborn, formerly in charge of peat investigations for U. S. Geological Survey.

"Technologic Aspects of Peat," by a representative of the Bureau of Mines.

"Peat Fuel Industry of Foreign Countries," by a representative of Department of Commerce.

"Classification of Peat and Muck Soils," by Milton Whitney, chief U. S. Bureau of Soils.

"Peat as a Fertilizer Ingredient," by Fred Wiedmer, president Wiedmer Chemical Co.

Cellulose Section, A.C.S., Plans Symposiums

The cellulose section of the American Chemical Society is arranging for two symposiums to be held at the time of the Pittsburgh meeting. The subjects—"The Constitution of Wood Cellulose" and "The Adsorption of Salts by Cellulose"—should prove of particular interest to pulp, paper and textile chemists. Among other scheduled speakers are Professors Bancroft, Holmes and Wise, and Doctors Johnson, Hawley, Esselen, Rue, Sherrard and Tingle.

Papers which are likely to arouse much interest and discussion are one by E. Sutermeister on "Research Problems in the Paper and Pulp Industry," and two by Alfred Tingle on "The Process in the Beating Engine and at the Wet End of the Paper Machine," and "The Reaction Between Aluminum Sulphate and Rosin-Size Solutions."

American Valuation Adopted for Dyes

Senate Accepts Flexible Tariff Proposal as Substitute for Embargo

American valuation as a basis for the application of import duties on coal-tar dyes and chemicals covered in sections 25 and 26 of the chemical schedule of the tariff bill was adopted by the Senate Aug. 11, without a record vote. Under the provisions of this so-called elastic tariff, the President has the power to transfer the basis of evaluation of these chemicals from foreign to American valuation, which is equivalent to an increase of more than 50 per cent of the duties in some cases.

It is provided that the President shall consider the difference in the wholesale selling prices of domestic and foreign merchandise in the principal markets of the United States, in ascertaining the difference in the costs of production here and abroad. The President is also directed to take into consideration the "advantages granted to a foreign producer by a foreign government or by a person, partnership, corporation or association in a foreign country." Senator Walsh of Montana declared that it would not be possible to obtain information as to wages, cost of raw materials and other items of production costs for the foreign products and offered a motion to strike out the whole paragraph. The motion was defeated by a vote of 42 to 20. Senator Smoot of Utah, a member of the Finance Committee, also acknowledged the difficulty of fixing the duties on patented products under the chemical schedule. "In fact," he said, "it is an utter impossibility to find the cost of production. In such a case, the only thing to do is to use the plan as outlined by the committee and get as near to the production cost as possible." He intimated that the determination of costs might be carried into the courts.

A Substitute for the Embargo

Senator McCumber, chairman of the Finance Committee, explained that the subdivision of section 315 covering the flexible tariff provision was intended to apply more specifically to dyes. "This method of meeting certain specified cases—not specified in the bill, but well understood by the Finance Committee—was in the first instance to prevent the necessity of continuing an embargo," said the North Dakota Senator. "It was intended to cover some of the chemicals and dyestuffs which might require a greater expansion of the duties than would be provided by increased duties on the foreign valuation basis.

"Of course, we have voted out the embargo proposition entirely and we have left the bill in such shape that it would be impossible to maintain an industry that we regard essential under the general rule which is provided in this amendment. That was the real purpose. It may be that the President might abuse that purpose. I do not think we will nor that anyone else will."

Chemistry Part of Curriculum of Every Course at Penn State

A course in chemisty is a requiremen in all the schools of the Pennsylvania State College, according to an announce ment made at that institution recently For most of the professions for whic the college offers training, a consider able knowledge of chemistry is neces sary.

In the school of agriculture, genera chemistry, agricultural chemistry, phys iological chemistry, food chemistry soil and fertilizer analysis, dairy chem istry, the chemistry of milling, and th chemistry of forest products, are amon the courses given. In the school o engineering, among the courses offere are general chemistry, the chemistry o sanitation, electrochemistry, industria chemistry, and a course in carbon com pounds. In the school of liberal art only a course in general chemistry i required, though others may be electe In addition to the general chemistr required in the school of mines, phys cal chemistry and other courses bearin on the subject of mining are give Chemistry, of course, plays the mos important part in the curriculum of th school of natural science. Househol chemistry and the chemistry of foo and nutrition are given for the depar ment of home economics.

Bureau of Standards Announces New Samples and Renewals

A new standard sample of tin-bas bearing metal No. 54 is now being i sued by the Bureau of Standards, wit a provisional certificate. This samp has the approximate composition: ti 88 per cent, antimony 7 per cent an copper 4 per cent. In addition, it co tains small amounts of lead, iron, bi muth and arsenic. The price of th sample per 140 grams is $2 prepa or parcel post C.O.D.

Benzoic acid No. 48a and benzoic ac No. 39a have been discontinued. Be zoic acid No. 39b replaces both of the and is issued for use both in acid metric and calorimetric work. Th price of this sample is $2 per 30 gram

The following renewals are al ready for distribution at the price $2 per 150 grams: Renewal No. 14b basic 0.8 per cent C steel No. 14 renewal No. 19b of acid 0.2 per ce C steel No. 19a; renewal No. 20b acid 0.4 per cent C steel No. 20a.

Sodium Nitrate Barge Fire En dangers Ships and Stores

Several ships and large quantities merchandise were endangered by t burning of a lighter loaded with sodiu nitrate in Erie Basin, New York Cit Aug. 11. The lighter was being load with the saltpeter from the Unit States Shipping Board freighter W Jaffrey when the fire broke out. T crew attempted to extinguish the flam with a hastily formed bucket briga but were forced to abandon the light and cast her off from the freight vess Shortly after the barge was abandon an explosion occurred which sank it.

Fraud Alleged in Salvage Deal for Old Hickory Powder Plant

Former Director of Sales of War Department and Business Men Indicted on Charge of Bid Containing "Joker"—Defendants Protest Innocence and Charge Politics

AN INDICTMENT has been returned by the special Grand Jury charging conspiracy in connection with the disposal of the Old Hickory Powder Plant at Jacksonville, Tenn. The indictment alleges that by an unlawful conspiracy among the three defendants, they participated in the sale and purchase of the plant for about $1,000,000 less than other bidders offered.

Largest Smokeless Plant

It will be recalled that the Old Hickory plant, the largest smokeless powder plant in the world, was erected for the government in 1918 by the du Pont Engineering Co. At the time of the armistice the plant was producing over 300,000 lb. of smokeless powder per day. It may also be remembered that a mild sensation was caused about two years ago by the theft of some of the platinum contact mass which was being recovered from the dismantled sulphuric acid units.

The plant was sold to the Nashville Industrial Corporation by the government. This corporation was organized by Ernest C. Morse, former director of sales for the War Department, said to be at present in Poland on business for the Foreign Export Supply Company, and Everly M. Davis and Alexander W. Phillips, trading under the name of the E. M. Davis Chemical Company of New York.

Charge "Trick" Bid

The method by which the defendants are alleged to have conspired to defraud the government is in the bid sent in by Davis and Phillips. It is charged that this bid contained many reservations and deductions which tended to make it appear that these two defendants were offering more for the plant than they actually offered. This so-called "trick" bid, the indictment charges, was, through Morse as sales director, approved by Secretary of War Baker on Oct. 9, 1920.

The contention of the government is that had it not been for the alleged unlawful acts of the defendants, the sale would have brought $4,700,000. The indictment has nothing to do with the sale of about $5,000,000 worth of surplus property at the plant which was disposed of before the plant itself was put on the market.

Outrage, Says Davis

Everly M. Davis, who claims to have been instrumental in bringing together certain business and financial interests in Nashville, Denver and New York for the purpose of purchasing the plant, is emphatic in his denial that there was anything criminal or even improper in the transaction. He accuses the government of making him and his associates the scapegoats in an attempt to impress the public with the results of its war fraud investigation.

"These indictments are an abominable outrage," said Mr. Davis. "There is no reason why I should be indicted. What we did was perfectly clean.

"As soon as I have a chance to read the indictment and see exactly what I am charged with I will make a statement giving the facts of the transaction in question, for I beleive the public should know the facts. An important public question of national interest is involved, in my opinion, and I think it will be interesting for the public to know how these so-called war frauds are being investigated.

Denies Bid Had "Joker"

Mr. Davis declares that the bid which was accepted by the government and which is now denounced as intentionally misleading was the result of painstaking efforts on the part of himself and capable associates. "It was our idea," he says to leave nothing to chance. We made our bid complete to the smallest detail."

As is well known, the government had already sold and contracted for the sale of a considerable quantity of the Old Hickory equipment and Mr. Davis claims that his bid very carefully stipulated that the returns from this property were to be deducted from the lump sum which was offered for the whole plant. "In other words," said Mr. Davis, "we did not want to buy a cat in a bag so we protected ourselves in the provisions of our offer. That is the grounds for calling ours a 'trick' bid."

Says Testimony Was Refused

Mr. Davis states that when he learned that the case was under investigation and that witnesses were being examined about it, he wired the District Attorney asking to be permitted to go before the Grand Jury and offering to waive immunity. Mr. Phillips did the same thing. This request was refused. They then asked the District Attorney for an opportunity to state the facts to him personally for any use he wished to make of them. This was likewise refused.

"From the unwillingness to hear the other side," says Mr. Davis, "the conclusion would seem to be unavoidable that the representatives of the government charged with making this investigation are more concerned with the obtaining of this indictment at this time than in establishing the truth; more interested in being able to emphasize to the public the fact that an indictment has been brought than in knowing themselves whether they have a proper basis on which to indict."

Government Action Against Foundation Proceeds Slowly

That the Attorney General has encountered more obstacles than he anticipated in his proceeding against the Chemical Foundation was indicated on Aug. 10, when in explaining the delay in filing the suits, he remarked facetiously that he is confronted in the Chemical Foundation matter with a "powerful combination of self-constituted and indefatigable philanthropists." Mr. Daugherty stated that he personally devoted three intensive hours on the bill of equity on Aug. 9. He did not say when the suit would be filed, but declared that the department was making haste slowly.

The office of the Alien Property Custodian is furnishing the Department of Justice detailed data on each of the patents, and it is estimated that in all they will cover at least seven thousand pages.

Since the administration's effort to secure the return of the patents several attempts have been made to obtain an expression from the National Research Council as to whether or not the Foundation has lived up to that portion of its charter that provides that the free net earnings of the corporation above 6 per cent are to be "used and devoted to the development and advancement of chemistry and allied sciences in the useful arts and manufactures in the United States."

The position of such officers of the Council as are in Washington is that this is a matter for the Interim Committee of the Council to pass. The Interim Committee will not meet until some time in September.

Chicago Section of A.C.S. Enters Plea for Dye Embargo

The executive committee and the councilors of the Chicago Section of the American Chemical Society have sent a telegram to the two Illinois Senators, McCormick and McKinley, urging them to support the proposed embargo on dyes. The telegram reads:

> Chicago Section American Chemical Society is thoroughly convinced that dye embargo is absolutely necessary for proper development of chemical industries and that it is to the decided advantage of American users of chemicals. Before it is too late we urge you to reopen the matter and do your utmost in action and support for the embargo.

The signers of the telegram included some of the most distinguished scientists in the West. Dr. Leech, chairman of the section, commenting upon the telegram, said that the executive committee and the councilors of the Chicago group of chemists feel that the interests, first, of public health demand the establishment of an organic chemical industry, which is "only possible if German unfairness is barred at our shores; second, national security and third, the economic returns and benefits from having our own industry and being free from a foreign monopoly."

Ellis Oil-Cracking Patents Subject of Suit

Standard Oil of New Jersey Charges Infringement in Cross Process of the Pure Oil Co.

The Standard Oil Co. of New Jersey has brought suit in the U. S. District Court, Southern District of Ohio, against the Pure Oil Co. of New York in order to restrain an alleged infringement of the Ellis patents for the cracking of petroleum distillates. The latter company is claimed to have been engaged in cracking oil at its plant at Heath, Ohio, under the Cross patents, which are controlled by the Gasoline Products Co., of 52 Broadway, New York City. The Standard Oil Co. claims that this process is an infringement on its so-called tube and tank method of oil cracking, which is broadly covered by the Ellis patents of 1913.

That the litigation may prove of considerable consequence to the petroleum industry is indicated by a statement from the Gasoline Products Co., which by agreement with the defendant is to bear the expenses of the suit. Officials of that company declared that the validity of the Cross patents had been passed on by some of the country's foremost patent authorities and that subsequently the process had been adopted by several of the independent refineries. The suit they believed to be nothing more than an attempt to hamper independent gasoline production.

Deny Monopolistic Control

The existence of any monopolistic control of cracking processes was immediately denied by the Standard company, which indicated that it was willing at all times to grant licenses under these patents. Its statement, in part, follows:

> It is not to be understood that the bringing of this suit indicates any intention or desire on the part of the Standard Oil Co. of New Jersey to monopolize the use of cracking processes of the type in question. The suit was deemed to be necessitated by the fact that certain interests in the oil industry have been persuaded to refuse to respect the rights vested in this company by the grant of the broad Ellis patents. Under the circumstances, this company felt compelled to seek legal redress.
>
> With regard to that considerable proportion of the industry which has evidenced that it intends to respect our patent rights, there is no disposition on the part of the company to maintain a monopoly of the use of the type of process in question or to impose burdensome or discriminatory terms of license. The company is, and has been, willing to grant licenses under its cracking patents on fair and reasonable terms.

Outline of Cross Process

The operation of the Cross process embraces the following features:

1. Heat is applied to the oil in tubes arranged in series. The tubes are placed horizontally in a heavily constructed, well-insulated furnace in such manner that should a tube fail the only damage is from loss of the tube, as the small amount of oil discharged is burned and mostly goes up the chimney or is discharged into a tank.
2. The oil is pumped through the tubes in one direction only and no oil that has undergone reaction with the separation of carbon is returned to the tubes.
3. Decomposition does not take place in the tubes sufficiently to deposit an appreciable amount of carbon.
4. The heated oil is passed from the tubes to a reaction chamber, where conversion of the heavy oil into gasoline takes place and where the carbon is deposited.
5. No heat is applied to the reaction chamber, but this chamber as well as all parts of the plant are heavily insulated against losses of heat to the atmosphere.
6. No distillation takes place from the reaction chamber or from any portion of the system, as this would retard the conversion by reason of its cooling effect.

Both processes are claimed to be particularly well adapted for use by the small refiner, since capacity and outlay for equipment are much less than for the better known Burton process.

Organic Chemical Manufacturers Pledge Support to New Chemical Division

That the chemical industry has already recognized the new Chemical Division of the Department of Commerce as a valuable aid to business is shown by the support accorded to C. R. DeLong, its recently appointed chief. Several representative organizations have offered their assistance in organizing and carrying on the work.

On Aug. 3 Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers' Association of the United States, pledged the whole-hearted support of the seventy-seven member firms of that organization. Furthermore he testified as to the value of the monthly statistics being compiled by the bureau and offered to assist in their dissemination while the work of organization is still under way. Dr. Herty's letter to Mr. De Long in part reads as follows:

> On behalf of the seventy-seven member firms of this organization I want to tender our whole-hearted support in the work of building up this division of the bureau, which I am confident will be of unlimited value in the development of the organic chemical industry in this country.
>
> Among the valuable pieces of information issued by the bureau in the past have been the monthly bulletins of statistics on imports and exports of dyes. Our manufacturers are very anxious to receive this information regularly and it occurs to me that while your work of organization is under way we could distribute this information to our members from this office if that were agreeable to you, later turning over our mailing list to your division so that the matter could go direct to our members.

The letter expressed the further hope that it would be possible to extend the statistical service to cover all synthetic organic chemicals.

Liquid Oxygen as an Explosive

Such promising results have been obtaned in the course of the experiments conducted by the Bureau of Mines in the use of liquid oxygen as an explosive that there is a widespread demand for further work along the same line. The demand is coming largely from the building and city improvement industries where there is need for an explosive possessing the minimum handling hazard.

Engineers Advocate National Hydraulic Laboratory

Would Create Facilities for Study of Problems of Water Supply and Flood Control

A national hydraulic laboratory, in which studies relative to the country's problems of water supply and flood control would be carried out, is to be advocated by Mortimer E. Cooley, president of the American Society of Civil Engineers, before a Senate sub-committee the latter part of this month.

A bill to create such a laboratory is now before the Senate. The sub-committee is composed of Senator Ransdell of Louisiana, Senator du Pont of Delaware and Senator McNary of Oregon, representing the Gulf, Atlantic and Pacific coasts. Dean Cooley and J. R. Freeman, of Providence, R. I., will make the initial presentation of the case for the laboratory, contending in behalf of the engineering profession and other national agencies that the laboratory would make it possible to concentrate attention on the scientific side of flood control and other hydraulic problems. Mr. Freeman is a national authority on water power and a year ago, as a member of the John Fritz Medal Board deputation, studied at first hand the power situation in European countries, particularly France.

At the last meeting of the executive board of the American Engineering Council, the Council's committee on water power, of which Colonel J. H. Finney of Washington is chairman, was directed to place before President Harding the facts of the situation with regard to water-power development in this country. The board's action, it was stated, was prompted by "the Federal Water Power Commission's lack of effective and permanent personnel." The water-power plan coincides with the American Engineering Council's reforestration movement, in which the engineers are co-operating with the U. S. Forestry Service, the Forestry Services of the states, universities and technical schools, and other groups such as farmers, railroads, the movies and lumbermen to conserve the country's forests.

The executive board of the Council, which is to meet in Boston, Sept. 8 and 9, has adopted a resolution declaring that stream flow conditions in many sections of the country vitally affect the welfare of the people in many ways. Loss of life and property damage resulting from floods, economic significance of water-power developments, industrial utilization, quantity, quality and possible contamination of municipal supplies, and interstate subsurface water supply were some of the ways by which, it was declared, grave problems are arising.

Dean Cooley, who has been holding a series of conferences with engineering leaders in New York, said that the whole question would come before the executive board of the Council in Boston next month.

Technical Photographic Society Announces Exposition Program

Preliminary announcement has been made of the program and exhibition plans of the Technical Photographic and Microscopical Society. In addition to other features of the program of interest to the technical photographer and microscopist as an adjunct of chemistry, the following papers have been scheduled:

"The Photomicroscopy of Paint and Rubber Pigments," by Henry Green of the New Jersey Zinc Company, Palmerton, Pa.

"Photomicrography in Pulp and Paper Research Problems," by Miss Eloise Gerry and Dr. E. M. Diemer of the Forest Products Laboratory, Madison, Wis.

"Handling of Motion Picture Films," by Dominic S. Mungillo of the Craftsmen's Film Laboratory, New York.

"Mechanics of Motion Picture Apparatus," by Clarence W. Gibbs of the Victor Animatograph Company, New York.

"The Motion Picture as an Art in Industry," by Alfred B. Hitchins, director of the Ansco Research Laboratory, Ansco Company, Binghamton, N. Y.

"Microscopy in Leather Tanning," by Guido E. Daub of A. F. Gallun Sons Company, Milwaukee, Wis.

"The Use of the Microscope in Textile Work," by Albert H. Grimshaw, of the Textile School, New Bedford, Mass.

"Protozoa and Rotifers: Studies in Microscopic Animal Life," by Philip O. Gravelle, South Orange, N. J. This paper will be illustrated with motion pictures.

In addition to the meeting sessions of the society at the Exposition, the organization will have an exhibit at which the advance in technical photography, microscopy, and in chemistry as a result of these two sciences, will be demonstrated. Many of the problems of the chemical consuming industries, particularly regarding the physical nature of raw materials and finished products, have received the attention of a number of members of the society and can be discussed with the investigators at the Exposition.

Will Establish Engineering Museum

Plans for the establishment of a national engineering museum, the first of the kind in the United States, are announced by the American Society of Mechanical Engineers. The collection, which will be part of the Smithsonian Institution's National Museum at Washington, will be started with various models, drawings, diplomas and medals that once belonged to Captain John Ericcson and Cornelius H. DeLamater, builders of the Monitor, and the pioneer engineers of America.

All the engineering societies in America have accepted the Mechanical Engineering Society's invitation to participate in assembling material for the museum.

Fire Prevention Exposition Planned in New York

Loss of $1,300,000 Daily by Fire Arouses Organizations to Educational Steps

Manufacturers of fire-resistive materials and of fire fighting and retarding apparatus will have the opportunity of taking part in a Fire Prevention Exposition to be held Oct. 2 to 7 at the Twenty-second Regiment Armory, New York City, where will be shown, by exhibit and demonstration, the vital part in the fight against the great annual fire loss played by fire-safe materials and apparatus.

The Exposition originated with the fire prevention committee of the National Association of Insurance Agents as part of its program of fire prevention activities. It has been endorsed by the National Fire Protection Association, the National Association of Credit Men, the International Association of Fire Engineers, the National Board of Fire Underwriters and other associations.

The problem of reducing the terrific strain on business caused by preventable fires that seem to be increasing each year is one that has engaged the attention of these organizations. At the present rate of burning, property worth $1,300,000 is being destroyed each day. So great has the strain on business become that on June 26, at the request of these organizations, Governor Ritchie, of Maryland, called a conference of the Governors of New York, New Jersey, Maryland and Virginia. This conference adopted a motion to present the matter of fire waste and conservation to the Chamber of Commerce of the United States and on July 12 a conference of representatives of the four associations named above and of the American Institute of Electrical Engineers, Railway Fire Protective Association, American Institute of Architects, American Society of Mechanical Engineers and the Boy Scouts of America was held at Washington. The Chamber of Commerce of the United States was asked to undertake the responsibility of educating organized business men to the huge annual tax caused by fires. The Chamber accepted this responsibility and plans are now under way for a national citizens' fire prevention campaign.

The peak of this year's effort will be reached during National Fire Prevention Week, Oct. 2 to 7, and the First Fire Prevention Exposition will be its greatest educational feature. It is purposed to show the latest ideas in fire-safe construction and also to demonstrate to the public the proper appliances to be used in fighting and preventing fires.

A lecture hall is in the armory building and it is planned to make each day of the Exposition a special day, with lectures and motion pictures in the lecture hall. A. E. MacKinnon, of 405 Lexington Avenue, New York, is chairman of the exposition committee.

Alpha Chi Sigma Members Will Register at Exposition

Members of Alpha Chi Sigma, the national chemical fraternity, who attend the Exposition of Chemical Industries in New York, Sept. 11 to 16, are invited to register at the booth occupied by *Chemical & Metallurgical Engineering*. The dinner which is planned for Thursday evening of that week will attract a number of members who will be in town for the Exposition. In order that arrangements may be made all members are requested to sign up in the register that will be available for that purpose at the *Chem. & Met.* headquarters on the first floor of the Grand Central Palace.

Meat-Packers Deny Control of Tanning Industry

Denying the charge that the tanning industry is controlled by powerful meat-packers, and resenting the inference that the meat-packers would destroy competition, the Institute of American Meat Packers has issued the following statement:

"The Institute of American Meat Packers is not concerned one way or the other in the proposed tariff or the absence of a tariff on hides but is very much interested in remarks about the packing industry made by Senator Walsh and published throughout the United States. Senator Walsh said that the big packers virtually control the tanning industry and that if there was a duty the small tanners would be driven out of business. This statement is erroneous; the packers big or small do not have any control of the tanning industry. The big packers, through tanneries in which they are interested both directly and indirectly, handle less than twenty per cent of the leather made in the United States and they are in keen competition with each other even in the handling of this small proportion.

"If there should be a duty on hides and this duty raised their price, the competition among the packers would result in passing the benefit along to cattle raisers. The effect would be slight, it is true, but cattle values fluctuate 5 and 10 cents per hundredweight at a time depending on the value of the meat and byproducts. Hence a slight increase in hide values would result in a slight increase in cattle prices and a proportionate increase in cost to to consumer. Competition keeps the packers' profit at a minimum. It is therefore unfair to say that small tanners will be squeezed out.

"The Institute resents any inferences that the packing companies could or would crush or destroy any industry. The charges that the packers have a monopoly power over the price of cattle, hides, meat or other products have been disproved again and again. This statement is issued not so much in criticism of Senator Walsh as it is to correct published inferences which reflect upon the commercial integrity of one of America's most important industries."

Pyrene Fire Extinguishers Reported Safe in Subway

New York Transit Commission Exonerates Tetrachloride in Recent Accident

After an investigation of the circumstances attending the fire in the New York subway some weeks ago, the Transit Commission has reported that all the illness and suffering of passengers was caused by smoke from burning insulation aggravated by the panic and haste with which they climbed 75 feet to the street, and that no serious amount of poisonous gases was generated by the Pyrene fire extinguishers. What fumes did come from the carbon tetrachloride used in the extinguishers were so diluted as to be negligible.

In preparing this report the commission had the services of experts from the Bureau of Mines and of consulting electrical engineers. The results of their investigations are summed up as follows:

There were apparently no really serious cases resulting from the effects of possible toxic gases.

The symptoms given in the hospital records can all be accounted for by the known effects of gases resulting from the burning of insulating materials, rubber, varnish and paint.

The symptoms are not characteristic of phosgene or tetrachloride poisoning.

The report calls attention to the work of the Materials Inspection Division of the commission in connection with the Bureau of Mines, which points out that Pyrene is particularly adapted to fires produced by electric short circuits because it is not a conductor. After stating that experiments will be made to find a better extinguisher, the report says:

"In the meantime our study of the results of the use of Pyrene in this instance conclusively shows that its use was in no way dangerous or even discommoding. The continued efficient operation of the subways is essential to the life of the city, and this efficient operation requires the use of some immediately available fire extinguisher in case of electric short circuits, which are always possible of recurrence. Tetrachloride is the best known and most universally accepted extinguisher for this purpose. Nothing has been discovered by the investigation to justify ordering its discontinuance."

Walter Bauer, president of the Pyrene Manufacturing Co. has asked the Transit Commission, President Frank Hedley of the Interborough, and Mayor Hylan to permit a public demonstration of the efficiency of the Pyrene fire extinguisher.

Civil Service Wants Food Chemist

The United States Civil Service Commission announces an open competitive examination for assistant chemist in the chemistry and physics of food preparation under the Department of Agriculture. The entrance salary will range between $1,980 and $2,400 a year.

Non-Metal Industries Appeal for Government Research Funds

Members of Congress from the states having deposits of the non-metallic minerals are receiving many letters urging that Congress provide money for certain fundamental statistical and research work in connection with the non-metals industries. Since the government is conducting such work in connection with many other industries, those interested in the non-metals feel that proper recognition has not been accorded them.

During the last fiscal year, the Bureau of Mines appropriation carried an item of $35,000 for work in the non-metals. The item was eliminated from the appropriations for the current fiscal year. Realizing that steps to secure an appropriation for the fiscal year beginning July 1, 1923, must be taken long in advance, the industries concerned with the non-metals are agitating the matter thus early in the hope that Congress may be so impressed that at least the $35,000 item will be inserted in the appropriation bill covering expenditures during the next fiscal year. There is a demand for statistics and research covering such minerals as clay, granite, trap rock, chalk, emery, corundum, garnet, phosphate rock, sulphur, mica, asbestos, limestone, molding sand, glass-sand, dolomite, barium, graphite, gypsum, and slate.

Personal

EDWARD F. BEALE, president of the John T. Lewis & Bro. Co., Philadelphia, Pa., manufacturer of paints, colors, oils etc., has been elected vice-president of the National Lead Co.

GEORGE T. BRISTOL, who has been with E. I. du Pont de Nemours & Co. for the past 10 years, specializing in matters pertaining to Fabrikoid, has been appointed manager of the company's Fabrikoid plant at Newburgh, N. Y.

H. A. BROWN, assistant sales manager of the trade sales division, paint department, of E. I. du Pont de Nemours & Co., has just returned from a 4 weeks' trip through the South.

L. T. BRYSON has joined the staff of Ivan Jones, Ltd., Calcutta, India, in the capacity of consulting chemist in charge of feed-water treatment.

J W. COCHRAN has resigned his position with the Wenger-Armstrong Petroleum Co. to become vice-president and director of the Gavin Oil Co., Chicago, Ill.

PHILIP T. DODGE, president of the International Paper Co., and ALLEN CURTIS, vice-president of that organization, sailed recently for a 2 months' tour of Europe. They will visit most of the big paper-making companies while abroad.

Dr. H. D. GIBBS, formerly chief of the Color Laboratory, Bureau of Chemistry, has severed his connection wit the Jackson Laboratory of E. I. d Pont de Nemours & Co., Wilmingto Del. His plans for the future have n been announced.

WILLIAM J. GRIER, of the North Bri ish & Mercantile Insurance Co., Ltd has accepted the invitation of the off cers of the Insurance Society of Ne York to deliver two lectures on "Chen ical Fire Hazards" before the senic class of the Insurance Institute America on Feb. 15 and March 1, 192

Dr. ARMIN R. GROB, formerly a dy stuff patent expert with the Society Chemical Industry in Basel, Switze land, has resigned from E. I. du Po de Nemours & Co., Wilmington, De His plans for the future have not bee announced.

Dr. ELLWOOD HENDRICK, consultin editor of *Chem. & Met.*, who sailed June 10 to attend the meeting of th Society of Chemical Industry in Gla gow, is not expected back until Sept.

Dr. EDWARD C. L. KRESSEL, former president of the Active Chemical C Camden, N. J., will act in the san capacity with the Consolidated Pro ucts Co. of New Jersey, which he h been instrumental in organizing manufacture a similar line of specia ties.

E. W. MCCULLOUGH has resigned director of the division of mining a metallurgy, Republic Creosoting Co., accept a position as consulting engine for refuse disposal with the India apolis City Sanitary Commission to d sign and construct a new garba reduction plant.

J. S. NEGRU, managing editor *Chem. & Met.*, who has been in Euro for the past 6 months, sailed fro Antwerp on Aug. 10. He is expect to arrive in New York about Aug. 1

Dr. WILLIAM H. NICHOLS, chairm of the board of the General Chemic Co., is to represent the chemical indu try on a joint committee composed members of the Society for the Prom tion of Engineering Education and the National Industrial Conferen Board which is planning to take the general problem of engineeri training for the industries. Amo others who have been selected to ser on behalf of industry are FREDERICK FISH, formerly president of the Ame ican Bell Telephone Co. and the Ame ican Telephone & Telegraph Co.; E. HERR, president of the Westinghou Air Brake Co. and of the Westinghou Electric & Manufacturing Co., a HENRY D. SHARPE, treasurer of t Brown & Sharpe Manufacturing Dr. F. W. MCNAIR, president of t Michigan College of Mines, has be appointed to represent the Society f the Promotion of Engineering Edu tion. Other educators will be chos from technical schools of the country.

WALTER C. TEAGLE, president of t Standard Oil Co. of New Jersey, N York City, has returned from a t to Europe.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Marketing Problems of the Sulphur Industry*

Production, Consumption and Distribution of a Raw Material for Many Important Industries—Price Range and Trend Toward Enlarging the Market

By Albert G. Wolf
Texas Gulf Sulphur Co.

MORE THAN 99 per cent of the sulphur mined in the United States and 75 per cent of the world's production comes from three mines on the Gulf coast. In the order of their present and probable future importance as sulphur producers these are the Texas Gulf Sulphur Co., Matagorda County, Tex.; the Union Sulphur Co., Calcasieu Parish, La.; and the Freeport Sulphur Co., Brazoria, Tex. These three mines supply practically all the sulpur used in this country. In this article the word "sulphur" is used to designate crude sulphur or brimstone, and not sulphur produced from sulphides of metals. Wherever tons are mentioned in connection with sulphur the unit of weight is the long ton or 2,240 lb.

Uses of Sulphur Are Many

It is no exaggeration to say that sulphur is a constituent of, or a necessary reagent in, the manufacture of a large proportion of the articles in common use today.

The list in Table I, though probably far from complete, gives a good idea of the multiplicity of specific uses of sulphur. Every item either contains sulphur or requires sulphur in its manufacture.

The industries that use sulphur most are those which burn it to form sulphur dioxide, and employ that gas in their operations. These account for 75 per cent of the sulphur consumption in this country; the principal ones are the sulphuric acid, paper, chemical, and fertilizer industries.

TABLE I—LIST OF PRODUCTS IN THE MANUFACTURE OF WHICH SULPHUR IS REQUIRED

Acids	Hose
Alum	Insecticides
Aniline	Leather
Artificial silk	Livestock food
Belting	Lubricating oils
Binding medium	Matches
Bleaching materials	Medicine
Celluloid	Paints
Cements	Paper
Chemicals	Photo supplies
Dyes	Plastic (wood pulp)
Ebonite	Poison (rat and other)
Elastics	Preservative for food
Explosives	Reagents, laboratory
Fabrics	Rubber products
Fertilizers	Shoe polish
Films, moving picture	Soap
Fire extinguishers	Sodium thiosulphate
Fireworks	Steel (pickling)
Fumigating reagents	Storage batteries
Fungicides	Sugar
Gasoline	Textiles
Galvanized iron	Tires
Glue	Weed killer
Glycerine	

The industries, in the order of their commercial importance, that purchase sulphur as a "raw material" are:

1. Acid phosphate.
2. Paper.
3. Chemicals (other than sulphuric acid).
4. Sulphuric acid (other than for industries enumerated in this list).
5. Agriculture (other than acid phosphate).
6. Rubber.
7. Galvanizing.
8. Explosives.

This order, of course, is subject to change from time to time; and data for a more detailed tabulation of the sulphur-using industries are difficult to obtain. Furthermore, some of the industries are so interrelated that it is difficult to segregate the figures of consumption. The manufacture of sulphuric acid, under item 4 above, is by far the most important sulphur-consuming industry in the United States.

Geographic Distribution

Sulphur is sold to consumers in almost all the Eastern and Southeastern states, most of the Central, and some of the Western states; likewise in several provinces of Canada and states in Mexico. In the United States, by far the largest proportion is sold east of the Mississippi River. The major buyers may be divided roughly into three groups: The paper manufacturers of the New England states and eastern Canada, the chemical manufacturers of the Eastern states, and the acid posphate manufactures of the Southeastern states.

Lesser groups consist of the various industries of the Great Lakes region; the zinc, powder and chemical companies of the Central states; the powder, pulp and spray manufacturers of the Pacific coast; and various industries of British Columbia. Some shipments reach South Africa, the Hawaiian Islands and Australia.

The Mines Are the Principal Marketing Points

The primary marketing points are the three mines. From these, shipments are made directly to consumers. Secondary marketing points are the Gulf ports of Galveston, Texas City and Sabine, from which shipments are made to various foreign countries; and the Atlantic coast ports, whence shipments are again made by rail.

In the past the annual consumption of sulphur has been variable. As only 3 years has passed since the war, three

Editor's Note.—This article is abstracted from one of an important series on the marketing of minerals which is now appearing in the *Engineering & Mining Journal-Press.*

TABLE II—STATISTICS OF SULPHUR PRODUCTION AND CONSUMPTION

Year	Production in Tons World	United States	Domestic Shipments	Gross Value	Per Ton Value
1909	804,690	273,983	258,283	$4,783,000	$18.52
1910	775,286	247,060	250,919	4,522,000	18.02
1911	764,358	205,066	253,795	4,573,000	18.02
1912	773,436	287,773	305,390	5,289,000	17.32
1913	793,645	491,080	319,333	5,614,000	17.58
1914	863,143	417,690	341,985	6,214,000	18.17
1915	846,412	520,582	293,803	3,955,000	13.46
1916	1,199,842	649,683	766,835	12,247,000	15.97
1917	1,548,023	1,134,412	1,120,378	23,987,000	21.41

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	150.87
Last week	152.08
August, 1921	158
August, 1920	264
April, 1918 (high)	286
April, 1921 (low)	140

Notwithstanding slight advances in the prices for glycerine, caustic soda and linseed oil this index number has continued its downward trend. The decrease in cottonseed oil, which is one of the most sensitive of the index commodities, is principally responsible for the decline.

TABLE III—SULPHUR EXPORTS AND IMPORTS OF THE UNITED STATES

Kind of Imports	1916 Tons	1916 Value	1917 Tons	1917 Value	1918 Tons	1918 Value	1919 Tons	1919 Value	1920 Tons	1920 Value
Crude	21,510	$364,787	973	$20,176	55	$1,692	77	$1,997	46	$1,722

Total	22,456	$404,784	1,010	$29,340	82	$9,542	101	$8,633	138	$26,828
Exports	128,755	$2,505,857	152,736	$3,500,819	131,092	$3,626,638	224,712	$6,325,552	477,450	$8,994,350

abnormal years, and as complete statistics are not yet available for 1921, it is difficult to form an estimate of future requirements. It is probably safe to say that the normal consumption in the United States and Canada will be 750,000 tons per year, and by the rest of the world 250,000 tons of sulphur.

Yearly and Seasonal Fluctuations

The fluctuations in the demand for sulphur are of two kinds, yearly and seasonal. The former is influenced chiefly by general business conditions.

Seasonal fluctuations in demand are not great except in a few industries. The most important of these is the paper-pulp industry. Many of the mills accumulate their supply during the summer months because of the closing of navigation later by ice. Acid-phosphate manufacturers take between 15 per cent and 20 per cent of the total sulphur mined in the United States; as their product is sold largely during the early spring months, their manufacturing season, and consequently their purchasing of sulphur, is most active in the fall and winter months.

Problem Is to Enlarge the Market

The great marketing problem of the sulphur producer is to find an outlet for a sufficient tonnage of his product to permit operating at a profit when selling at a price per unit that will make the crude sulphur more desirable than pyrite. The potential production of the domestic mines is 2,500,000 tons per year, whereas the actual production, at present, is not over half that. In the near future the largest annual consumption of American sulphur, both domestic and foreign, that can be expected is approximately 1,000,000 tons.

In addition to this main problem each producing company has its own individual problem in obtaining its share of the sulphur trade without resorting to "cut-throat" tactics, which would lead to the undoing of all of them. The market is not influenced by middlemen, because almost all crude sulphur is sold directly to the consumer.

The one great influence on the price of sulphur, in addition to the general demand, is the price of pyrite. Sulphur is in direct competition with pyrite in the acid-making industry of the United States and Europe and in the paper-pulp industry of the Scandinavian countries. One-half the 1,000,000 tons sold in this country in 1920 was used in sulphuric-acid manufacture. It is possible that sulphur from the United States may replace pyrite to a greater extent than at present in the manufacture of sulphuric acid in Europe.

Table III, from *Mineral Industry*, vol. 29, gives the exports and imports of all classes of sulphur of the United States, and shows clearly that foreign competition has no influence on the price in this country now.

The efficient methods of production which have enabled the American producer to compete successfully with pyrites, both domestic and Spanish, in certain industries, have also made it possible to invade to an increasing extent the European market, formerly supplied entirely by the Sicilian mines.

The New York Market

New York, Aug. 14, 1922.

The continued shortage of coal has brought about additional changes in the chemical market during the past week. Producers have curtailed production to a considerable extent and the alkali export market for caustic soda was sharply advanced. The domestic price, however, has remained practically unchanged, although the demand has shown a decided improvement. Prices on yellow prussiate of potash were fractionally higher, under a better consuming demand and reduced spot supplies. White powdered arsenic was advanced by leading producers and importers. A large volume of business was reported transacted during the interval. Bichromates of soda and potash have maintained recent advances, and the market is in a very tight position for spot material. White granular sal ammoniac is rather unsettled on spot. The gray variety, however, is exceedingly strong, with domestic factors asking up to 8¼c. per lb. Acetate of soda is very firm and several producers report a well sold up condition. Bleaching powder is another item that has shown exceptional improvement and is meriting added interest from the consuming industries. Oxalic acid is being held at the recent advance and buyers are showing an eager desire for available spot goods.

General and Special Chemicals

Acetate of Soda—The market is very strong on spot and factors report a well sold up condition. Odd lots range from 6@7¼c. per lb., depending upon seller. A much higher market is expected shortly.

Arsenic — Leading producers named higher figures at 8¼c. per lb. The consuming demand has been very brisk of late. Shipments from abroad are quoted around 7½c. per lb.

Bleaching Powder — Although prices have not advanced from former levels, the demand continued very strong. Prices ranged around $1.60 per 100 lb. f.o.b. works.

Caustic Potash—Material on dock is held around $5.60 per 100 lb. for the 88-92 per cent. Shipment goods are quoted at 5½c. per lb. c.i.f. New York. The demand is somewhat limited.

Caustic Soda — Export prices were noticeably advanced presumably in order to conserve the supplies for domestic consumption. Spot goods are very limited. The export price is around $3.65@$3.70 per 100 lb. Odd lots for domestic use are held at $3.75 per 100 lb.

Prussiate of Potash — Quotations were advanced early in the week and spot goods brought 32¼c. per lb. Local stocks were reduced considerably.

Prussiate of Soda — Prices during part of the week were up to 21½c. per lb., but later were heard around 20c. per lb.

Sal Ammoniac—Imported white granular was fractionally lower on spot at 6⅛c. per lb. The gray material was rather scarce and the market was firmly maintained. Domestic producers of gray reported 8¼c. per lb. as the general quotation.

Vegetable Oils

Linseed Oil — Spot material during the early part of the week was offered as low as 84c. per gal., but was again advanced to 88c. per gal. by leading crushers. The stronger feeling was attributed to the prospects of an early tariff adjustment and a revival of interest from consumers. Imported oil was offered for August shipment at 82c. per gal., present rate of duty, c.i.f. N. Y.

Castor Oil — Producers advanced prices ¼c. per lb. on all grades of oil, establishing the market on U.S.P. at 13c. per lb. and the No. 3 grade at 12¾c. The advance was due to the higher cost of castor beans. Demand was rather active.

Coconut Oil — Although the market was somewhat unsettled, prices were steady in all quarters, due to the absence of any selling pressure. Resale offerings were not plentiful. Ceylon type oil in barrels was held around 8¾c. per lb., with the Cochin at 9c. per lb.

Corn Oil — There were offerings of August shipment of the crude at 8¼c. per lb., sellers' tanks, f.o.b. Chicago. The demand was of a routine nature.

Peanut Oil — The market for the crude oil was quiet because of the scanty offerings. Mills quote 9@9¼c. per lb., crude oil, tank cars for prompt shipment. Refined oil on spot was held around 12c. per lb.

The Chicago Market

CHICAGO, ILL., Aug. 10, 1922.

But little change could be noticed in the local chemical market during the past 10 days. Prices were a little stronger and the inquiry was reported as better, but no one had more business than he could take care of. Incoming freight was being delayed, which doubtless had much to do with the firmer prices, and again, stocks in some quarters were quite limited. An improvement in consumers' business was reported which was not to any extent reflected in the raw material markets. One of the most noteworthy developments is that the buyer is no longer haggling over prices to the extent that he did in the past.

General Chemicals

Caustic soda in the face of short supplies showed signs of firmness. Ground 76 per cent material was available at $4.35 per 100 lb. and the solid at $3.80. *Caustic potash* was also very firm, with only moderate supplies on spot at 6½@7c. per lb., basis 88-92 per cent. There was a fair inquiry for *soda ash*, and 58 per cent material in single-barrel lots was quoted at $2.35 per 100 lb. *Sal soda* also enjoyed a fair inquiry and was available at $1.90.

The movement of alums was reported as slow, with no change in prices. *Potash alum* lump was quoted at 4½@5c. per lb. and the powdered at 5½@6c. *Sal ammoniac* was firmer, with supplies lighter than for several weeks. The white granular 98-100 per cent material was quoted by leading interests at 7¾@8c. per lb. *White arsenic* displayed signs of firmness and the shortage of supplies forced the price to 8½@9c. per lb. *Barium chloride* was available in small or moderate lots at $100@$105 per ton. *Copper sulphate* was quite scarce and the price was very firm at 7@7½c. per lb. *Carbon bisulphide* was also quite firm at 7@7½c. per lb. *Carbon tetrachloride* moved only in a sluggish way and the price was weak at 9½@10c. per lb. *Formaldehyde* showed no change for the better and moved only in a small way at 9c. per lb. in single barrel lots. *Furfural* was quoted at 35c. per lb. in thousand-pound lots. *Glycerine* was very firm, and supplies were reported to be moving very well at 16½@17c. per lb. for the c.p. material in drums. *Lead acetate* was in poor demand and only small lots moved at 11@12c. per lb. *Red phosphorus* moved only in a small way at 25@26c. per lb. *Phosphorus pentoxide* was offered at 35c. per lb.

Bichromates were quoted higher by most holders, although the movement showed no improvement. *Potassium bichromate* was quoted at 11¼@11¾c. per lb., and the soda at 8¾@9¼c. in single-cask lots. *Red prussiate of potash* continued almost unavailable with only very small supplies on spot at 90c.@$1 per lb. *Yellow prussiate of potash* was in fair demand and the price was steady at 32@35c. per lb. *Permanganate of potash* moved only in a routine way and supplies of the U.S.P. small crystals were held at 16@16½c. per lb.

Linseed Oil and Turpentine

The movement of *linseed oil* was restricted to small quantities for immediate consumption and nearly all factors predicted lower prices. The boiled oil in single-drum lots was offered today at $1.02 per gal. and the raw in similar quantities at $1.

Turpentine was in a position similar to linseed oil, with most factors saying that the price was too high and freely predicting a considerable decline. Only small quantities moved to the consuming trade at today's price of $1.22 per gal. in single-drum lots.

The Iron and Steel Market

PITTSBURGH, Aug. 11, 1922.

Production of steel ingots in July was at an average rate of about 36,000,000 tons a year, against rates of 36,600,000 tons in June, 36,400,000 tons in May and 35,000,000 tons on April 1, when the coal strike started.

Production was not, however, at anything like a uniform rate during June and July. The rate increased toward the close of June, while in the latter part of July it dropped off rather sharply. A fair guess would be that the rate was 37,000,000 tons July 1 and 34,000,000 tons July 31, with a decrease to 30,000,000 tons at present.

Knowledge of Steel Consumption Lacking

The disposition of market reviewers at a time like this, when industrial operations are restricted by physical causes, is to stress the curtailment in production of the commodity being reviewed and to touch lightly on the curtailment in its consumption. If the reviewer were considering agricultural implements or automobiles, he would probably be full of the idea that production of these articles is hampered by the scarcity of coal. That there is a reduction is already established.

Apart from unconscious bias, facilities are lacking for comparing steel production with steel consumption, because there is more or less definite information as to steel production, while the operation of the thousands of steel consumers throughout the country cannot be viewed. Some information is available to steel mills, though it is not freely disseminated, but even this information is far from representative, because the average consumer, observing that steel is scarce, is disposed to retain or perhaps even increase his stocks. After every period of heavy steel demand there is an unexpectedly heavy liquidation of stocks, during which time demand upon the mills is less than the current consumption.

The present demand for early deliveries of steel products, at premium prices, is not necessarily misleading, but it may mislead through its not being studied on a comparative basis.

Buying for late delivery, practically "delivery at mill convenience," is light relative to a normal demand, but not particularly light for this time of year. The Steel Corporation's bookings are on the whole rather large. The unfilled tonnage at the end of July is reported at 5,776,161 tons, representing an increase during July of 140,630 tons, equal to 11 per cent of the month's capacity, and as shipments were about 75 per cent of capacity, the total bookings in the month were about 86 per cent of capacity, bookings in previous months, similarly computed, being 103 per cent in June, 86 per cent in May, 115 per cent in April, 90 per cent in March and less than 50 per cent in each of the 17 months preceding, since September, 1920. July bookings of independents were not nearly as heavy as those of the corporation.

The minimum on bars, shapes and plates has advanced from 1.70c. to 1.80c. in the week and from 1.60c. to 1.80c. within 30 days. This is for delivery at mill convenience, technically, though in all probability the convenience of buyer is fairly well met also. Prompt deliveries are up to 2c. or higher. Hoops narrower than 1 in. are now squarely on a base of 2.75c., other hoops remaining on the 2.50c. base. Railroad spikes are up $2 a ton to 2.35c., while small spikes and boat and barge spikes are up $5 a ton to 2.75c. Cold-finished steel bars are up $2 a ton to 2.25c.

Possible Trend in the Future

The condition of the steel market late in the year, when the strikes will have passed into history, will depend largely on the mental attitude of buyers, formed by guesses as to what is to occur industrially in 1923. Nearly all the business for the remainder of the year, in the purchase and sale of mill products, is already done, and the pressure upon mills for deliveries will depend largely upon whether buyers are disposed to hold or increase their stocks or engage in another drastic liquidation such as characterized the year 1921.

All semblance of a forward market in pig iron has disappeared. Buyers would, of course, be very foolish to attempt to make forward purchases at this time, when there is scarcely any merchant pig iron production and when furnaces have no means of knowing when they will be able to get into blast again. The only pig-iron market is a prompt, practically a spot, market, purchases being from stocks, which are meager. Foundry iron is generally bought in single carloads. Naturally prices have advanced with facility. On the basis of last sales the valley market is quotable as follows: Bessemer, $27; basic, $25.50; foundry, $28; malleable, $29. Freight to Pittsburgh is $1.77 since July 1, not $1.76 as at first computed.

Offerings of Connellsville coke are insufficient to supply anything like a normal foundry demand, not to speak of blast furnace requirements at all. Foundry coke is about $15, but the price varies considerably with quality.

Salt cake (bulk)	ton	18.00 –21.00	—
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1.60 – 1.67	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1.75 – 1.80	1.85 – 2.35
Soda ash, dense, in bags, resale	100 lb.	1.85 – 1.90	1.95 – 2.40
Sodium acetate	lb.	.06½ – .06¾	.07 – .07¼
Sodium bicarbonate	100 lb.	1.75 – 1.85	1.90 – 2.30
Sodium bichromate	lb.	.07½ – .07¾	.08 – .08¼
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04¾ – .05¼
Sodium chlorate	lb.	.06¼ – .06¾	.07 – .07½
Sodium chloride	long ton	12 00 –13 00	—
Sodium cyanide	lb.	.19½ – .21	.21½ – .25
Sodium fluoride	lb.	.09½ – .10	.10¼ – .10½
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3.35 – 3.40	3.75 – 4.00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.70 – 3.75	3.80 – 4.00
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.80 – 3.90	4.25 – 4.40
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	4.40 – 4.60
Sodium hyposulphite	lb.	.02½ – .03	.03½ – .03⅝
Sodium nitrite	lb.	.07¾ – .08	.08¼ – .08¾
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03 – .04	.04½ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	—	.18 – .21
Sodium prussiate, yellow	lb.	.21 – .21½	.21⅜ – .22
Sodium silicate, (40 deg. in drums)	100 lb.	.80 – 1.00	1.05 – 1.25
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.90 – 1.00	1.05 – 1.50
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04 – .04½	.04½ – .05
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04¼
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05½ – .06
Sulphur, crude	ton	18.00 –20.00	—
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	—	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	2.00 – 2.15	2.20 – 2.70
Talc—imported	ton	30 00 –40 00	—
Talc—domestic powdered	ton	18.00 –25.00	—
Tin bichloride	lb.	.09 – .09¼	.09½ – .10
Tin oxide	lb.	—	.35 – .37
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran.	lb.	.5¾ – .06	.06½ – .06¾
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08½ – .08¾
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.14 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.30 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.65 — .67
Benzoate of soda, U.S.P.	lb.	.53 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lbc	.50 — .55
Beta-naphthol, tech	lb.	.22 — .25
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.21 — .22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.54 — .56
H-acid	lb.	.80 — .85
Meta-phenylenediamine	lb.	.85 — 1.00
Monochlorbenzene	lb.	.10 — .11
Monoethylaniline	lb.	1.00 — 1.20
Naphthalene crushed, in bbls.	lb.	.06 — .06¼
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.07¼ — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35

Nitro-toluene	lb.	$0.15 —	$0.17
H-W acid	lb.	1.15 —	1.30
Ortho-amidophenol	lb.	2.10 —	2.15
Ortho-dichlor-benzene	lb.	.17 —	.20
Ortho-nitro-phenol	lb.	.75 —	.77
Ortho-nitro-toluene	lb.	.10 —	.13
Ortho-toluidine	lb.	.12 —	.14
Para-amidophenol, base	lb.	1.25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.72 —	.80
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	.85 —	.90
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.16 —	.18
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.75 —	1.80
R-salt	lb.	.55 —	.60
Salicylic acid, tech., in bbls	lb.	.23 —	.24
Salicylic acid, U. S. P.	lb.	.25 —	.26
Solvent naphtha, water-white, in drums, 100 gal	gal.	.27 —	.32
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 —	.18
Sulphanilic acid, crude	lb.	.24 —	.26
Toluidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

PAPER—The Hinde & Dauch Paper Co., manufacturer of corrugated paper products, has advanced production to full capacity at its Gloucester City, N. J., works, with day and night working forces.

The United Paper Board Co., Wabash, Ind., has resumed operations at its plant with a full working force of about 150 men, following a curtailment since last June. It is expected to maintain capacity production for an indefinite period. The coating mills at the plant are on a full production schedule, giving employment to a large working force. Orders on hand insure continuance on this basis for some time to come.

CERAMIC—The Harbison-Walker Refractories Co., Pittsburgh, Pa., is developing maximum capacities at its different plants in central Pennsylvania, and incoming orders are considerably in excess of production. A scarcity of labor in the vicinity of Mount Union, Pa., is handicapping the output at plants in this district.

Employees of the Toronto Fire Clay Co., Toronto, O., out on strike for 2 weeks past, have returned to the plant. The men have been granted an increase in wages of 5c. an hour.

Lack of fuel in the vicinity of Cleveland, O., has caused the Akron Sewer Pipe Co. to close two of its plants at Urichsville. The Cleveland Builders' Supply & Brick Co. has been compelled to curtail production at three of its local brick-manufacturing plants.

RUBBER—The Lycoming Rubber Co., Williamsport, Pa., has resumed operations at its plant, on a full-capacity basis, following a few weeks' shut down.

Automobile tire production at Akron, O., and vicinity during July broke all previous records, with gross output at the different mills for this month estimated at 2,750,000 tires. Up to the present time more than 11,000,000 tires have been manufactured in this section, dating from the first of the year. The leading companies are maintaining the following daily production schedules: B. F. Goodrich Co., 20,000 tires; Firestone Tire & Rubber Co., 25,000; Goodyear Tire & Rubber Co., 26,000; and the Miller Tire & Rubber Co., 7,500.

IRON AND STEEL—The Tennessee Coal, Iron & Railroad Co. is making ready for the immediate blowing in of its No. 1 blast furnace at Ensley, Ala.

The Follansbee Brothers Co., Pittsburgh, Pa., has resumed production at its sheet and tinplate mills at Toronto, O., and Follansbee, W. Va., following a temporary shut down due to coal shortage.

The Bethlehem Steel Co., Bethlehem, Pa., is maintaining an operating schedule of about 80 per cent of capacity at its local mills.

A shortage of coal and coke has caused the Midvale Steel & Ordnance Co., to bank its No. 2 blast furnace at Coatesville, Pa. It will remain idle until conditions improve.

The Brier Hill Steel Co., Youngstown, O., has resumed operations at six of the eleven open-hearth furnaces recently closed down on account of fuel shortage. Gas burners have been installed to insure continuous service.

Following continuous operation for a number of weeks past, the Illinois Steel Co., has banked two of its furnaces at South Chicago, Ind., and two at Gary, Ind., reducing production to an 84 per cent of normal basis. Fuel shortage is responsible for the curtailment.

The American Steel Foundries, Chicago, Ill., is maintaining production on a basis of from 75 to 80 per cent of capacity at its different plants. The company has a coal supply on hand sufficient to insure continuous operation for about 60 days, and has booked orders to allow production on the basis noted for the remainder of the year.

The Inland Steel Co., Chicago, Ill., is holding operations on a basis of 65 to 70 per cent, the same rate as has been prevailing for some time past.

Coal and coke shortage has caused the Jones & Laughlin Steel Co., Pittsburgh, Pa., to bank one of its Eliza blast furnaces.

The Trumbull Steel Co., Youngstown, O., is maintaining capacity production at its mills, with one furnace now idle on account of fuel shortage.

The Youngstown Sheet & Tube Co., Youngstown, O., is continuing at three of its six blast furnaces, and will increase operations as soon as fuel is available.

METALS—The American Smelting & Refining Co. is running full at its smelter of seven lead furnaces at its plant at Chihuahua, Mexico. The tonnage output is larger than ever before in the history of the plant.

Owing to inability to obtain railroad shipping facilities on account of the strike, the Aluminum Co. of America, Pittsburgh, Pa., has closed down its sheet mill at Alcoa, near Knoxville, Tenn.

The Anaconda Copper Mining Co. is resuming operations at its Emma properties at Butte, Mont., closed down since January, 1921, and devoted to zinc, silver and lead production. About 125 men will be employed. This is the fourteenth property of the company to be reopened in this district.

MISCELLANEOUS—The American Vulcanized Fiber Co., has reached capacity production at its plants at Wilmington and Newark, Del., for the first time in more than a year past.

The Long Valley Paint Co., Hancock, Pa., is arranging for immediate resumption of operations at its local plant, following a long period of idleness.

The Atlas Powder Co., Tamaqua, Pa., has increased operations at its local mills from 5 to 6 days weekly. Incoming orders insure this rate of production for some time to come.

Despite the general custom of closing down among the glass plants at Millville, N. J., the last of July of each year, a number of plants are continuing owing to the heavy orders on hand. These include the Millville Bottle Works, which will keep two furnaces active; and the F. C. Wheaton Co., manufacturer of druggists' glassware.

Construction and Operation

Arkansas

FORT SMITH—The Equitable Powder Co. has tentative plans under consideration for the rebuilding of the portion of its plant, destroyed by fire, caused by an explosion, July 28. An official estimate of loss has not been announced.

California

PITTSBURG—The Pioneer Rubber Co., 68 Sacramento St., San Francisco, has taken bids and will soon award contract for the construction of its proposed local building, 1-story, 80x200 ft., estimated to cost about $150,000. Benjamin G. McDougall, 381 Bush St., San Francisco, is architect.

LOS ANGELES — The Egyptian Lacquer Mfg. Co., 5 East 40th St., New York, N. Y., has completed plans and is taking bids for the construction of a new 1-story building, 50x100 ft., on Maple Ave., near 11th St., Los Angeles, for a Pacific Coast works. Mott M. Marston, 533 San Fernando Bldg., Los Angeles, is architect.

SAN FRANCISCO—The Pacific Gas & Electric Co., 445 Sutter St., will construct an artificial gas plant at Army and DeHaro Sts., to cost close to $100,000.

Connecticut

MIDDLETOWN—The Standard Oil Co., 26 Broadway, New York, N. Y., has plans nearing completion for the construction of a new oil and gasolene distributing plant on the Connecticut River, near Middletown. It is said that the works will cost in excess of $3,000,000, with equipment.

Florida

ST. PETERSBURG—The Texas Refining Co. has plans under way for the construction of a new oil plant on site acquired at 8th St. and 2nd Ave. The initial works will cost about $30,000. It is also planned to construct a gas-plant at this same location.

Indiana

TERRE HAUTE—D. R. Ulmer, Terre Haute, and associates, have organized a new company for the operation of a local plant for the manufacture of sewer pipe, tile, conduit and other burned clay products. The initial works will have an output of about 4,000 lengths of material per day, and this will be increased to about 9,000 at an early date. Ernest Cox will be plant superintendent in charge.

Louisiana

HAYNESVILLE—The Standard Oil Co. of Louisiana, New Orleans, will commence the immediate construction of a new distributing plant at Haynesville, near Shreveport, to provide a total storage capacity of close to 3,000,000 bbl. of oil in this district. The plant with equipment will cost in excess of $150,000.

Maryland

ILCHESTER—The Mineral Potash Co., 714 Equitable Bldg., Baltimore, has revised plans in preparation for the construction of a new plant at Ilchester, and will call for bids early in the fall. It will be 1-story, 50x150 ft., and is estimated to cost about $55,000. Louis A. Hazard is president.

SALISBURY—The Hearn Oil Co., 3rd and Commerce Sts., Wilmington, Del., has purchased property on Mill St., and has plans under way for the construction of a new distributing and storage plant with capacity of about 25,000 gal. The initial works will cost close to $40,000.

BALTIMORE—The Edro Richardson Brass Co., 318 North Holliday St., will break ground at once for the construction of a 1-story addition to its brass foundry, to be located on Monument St., and estimated to cost about $40,000. Improvements will be made also in the present building. The general contract has been let to J. E. Stansbury, 2852 Pennsylvania Ave.

BALTIMORE — The Baltimore Concrete Products Co. has filed plans for the construction of a new 1-story building on Kate Ave. and the line of the Western Maryland Railroad, to be 35x80 ft.

BALTIMORE—The board of directors, Loyola College, 700 North Calvert St., has awarded a contract to Henry Smith & Sons, 7 East Redwood St., for the construction of a new 2-story chemistry building, to cost about $200,000. Otto G. Simonson, Casualty Bldg., is architect.

Massachusetts

SALEM—The Wetan Leather Co., Danversport, Mass., has acquired a factory at Hardy St. and Central Ave., Salem, heretofore occupied as an extra works by the Budgell & Harrigan Co., for the establishment of a new plant to replace its Danversport works, recently destroyed by fire. Possession will be taken at once and necessary equipment installed.

PEABODY—The Weber, Laemmle Tanning Co., Salem, has acquired the local plant of the Armstrong Leather Co., and will remove its present works to this location at once. Increased facilities will be provided for production. George J. Laemmle heads the company.

GREENFIELD—The Deerfield Valley Paper Co. has been organized to take over and operate the plant of the Monroe Bridge Paper Co., Monroe Bridge, near Greenfield. Increased manufacture will be arranged.

PEABODY—The Chain Leather Co. has acquired property at 55 Walnut St., for the establishment of a new works.

Michigan

HANCOCK—The chemical laboratory at the Hancock High School was destroyed by fire July 25, in connection with a partial destruction of the building, with total loss estimated in excess of $200,000.

CLAWSON—A filtration plant will be installed by the Common Council in connection with its proposed new water system. Bonds have been voted.

Mississippi

HATTIESBURG—The Hattiesburg Pine Oil Co., recently organized, is arranging a list of equipment for installation at its proposed new local plant for the manufacture of pine oil, tar, rosin oils, turpentine, etc., to include complete refining equipment, two 52 ft. retorts, pumping apparatus, and power house equipment. The mill will cost close to $100,000, with machinery. The company is capitalized at $425,000. Paul S. West is head.

Missouri

ST. LOUIS—The Benjamin Moore Paint Co., 1600 South 2nd St., has awarded a contract to the Hall & Mackay Construction Co., St. Louis, for the rebuilding of the portion of its plant recently destroyed by fire. The work will cost about $75,000. Mauran, Russell & Crowell, Chemical Bldg., are architects.

ST. JOSEPH—Fire, Aug. 2, destroyed the local lard refining plant of Morris & Co., Union Stock Yards, Chicago, with loss estimated at about $100,000, including equipment. It is planned to rebuild the works.

Montana

GREAT FALLS—The Anaconda Copper Mining Co., 25 Broadway, New York, N. Y., has tentative plans under consideration, for the construction of a new brass fabricating plant at its mills at Great Falls. It is estimated to cost in excess of $500,000.

New Jersey

GLOUCESTER CITY—The Armstrong Cork Co., 24th St., Pittsburgh, Pa., with district plant at Camden, N. J., will remodel and improve the local building at Delaware Ave. and Ellis St., formerly used by the Ancona Printing Co., recently acquired. For the present the structure will be used as a general service and operating building, and later machinery will be installed to convert into a manufacturing works.

TRENTON—The Panelyte Board Co., Smith Bldg., 119-25 North Montgomery St., lately organized with a capital of $300,000 in preferred stock and 4,000 shares of common stock, no par value, has acquired property on Whitehead Road for the construction of a new plant for the manufacture of fiber board and other fiber products. The initial plant unit, plans for which are being prepared, will be equipped to give employment to about 60 men. D. Manson Sutherland, Jr., has been elected president and manager of the new company; other officials include George G. Connor and S. E. Kaufman.

New York

YONKERS—The Arlington Chemical Co., 100 Hamilton St., is completing plans and will take bids before the close of the month for the construction of a new 4-story plant on Harriett St., Yonkers, to be equipped for a general line of chemicals and chemical byproducts. Timmis & Chapman, 315 5th Ave., New York, are architects. John E. Andrus heads the company.

ROCHESTER—Fire, Aug. 1, destroyed a portion of the plant of the Rochester Composite Brick Co., with loss estimated at about $100,000, including equipment and stock.

BUFFALO—The Upco Petroleum Co. will commence the immediate construction of its proposed new local plant on site recently acquired on Military Road. The company has a tract of about 2 acres of land, and expects to utilize it entirely for different plant units.

LONG ISLAND CITY—The Borough Engineering Department has plans in progress for the construction of two incinerating plants to be located at Woodhaven and Winfield respectively; each plant will comprise two retort units with total capacity of about 100 tons a day, and is estimated to cost about $275,000. Edward Richardson, Flushing, L. I., and Joseph P. Powers, Rockaway, L. I., are architects.

Ohio

DELAWARE—The Delaware Brass Co. has completed plans and is taking bids for the construction of a new 1-story plant on local site, 50x150 ft.

KENMORE—The Palmer Match Co., 9th floor, Second National Bank Bldg., Akron, O., Charles A. Palmer, president, is arranging a list of equipment for installation at its new plant at Kenmore, for which ground recently was broken, to include complete sulphur house apparatus, mixing machinery and other mechanical equipment. The plant will be 2-story and basement, and is estimated to cost in excess of $500,000. Henry & Murphy, Second National Bank Bldg., Akron, are engineers.

Oklahoma

DEWEY—The Co-operative Rubber Co. will commence the immediate construction of a new plant on local site for the manufacture of a general line of rubber products.

DUNCAN—The Pauline Oil & Gas Co. has commenced the construction of a new oil-refining plant on property lately acquired about 5 miles south of Duncan. The plant will be equipped to handle about 700 bbl. of crude oil per day, and is estimated to cost close to $70,000.

CUSHING—The Cushing Refining & Gasoline Co., a subsidiary of the Mulberry Oil Co., capitalized at $500,000, has acquired the local oil refinery of Gustafson & Spencer, with capacity of about 1,500 bbl. per day. The company will make extensions and improvements and will operate the plant in connection with its new 3-unit gasoline compression plant, now in course of construction at Ingalls, Okla.

Oregon

PORTLAND—The Steno Carbon Paper Co. has awarded a contract to the Hurley-Mason Co., Gasco Bldg., for the construction of a new 1-story plant on the Sandy Blvd., for the manufacture of carbon and other papers. It will cost about $60,000, including equipment.

Pennsylvania

LANCASTER—A 1-story foundry will be constructed by the Burnham Boiler Works, Irvington-on-Hudson, N. Y., in connection with its new local plant on the Dillville Road, Lancaster, estimated to cost about $200,000. Frank D. Chase, Inc., 645 North Michigan Ave., Chicago, Ill., is architect and engineer.

PHILADELPHIA—The Philadelphia Paper Mfg. Co., Nixon St. and River Road, will commence the immediate erection of a new 1-story building at its plant.

PHILADELPHIA—The Paper Manufacturers' Co., 526 Cherry St., with plant at 13th and Noble Sts., has purchased property at 408-18 North 5th St., for a consideration of about $72,500, and will use the land for proposed plant expansion.

Texas

NAVASOTA—The Planters' Cotton Mill Co. has tentative plans under consideration for the rebuilding of its local plant, partially destroyed by fire recently, with loss estimated at close to $60,000

NILE CITY—The Kerr Tire Co. has acquired a local site, and has work under way on a new plant for the manufacture of automobile tires, tubes, etc. The initial works will be equipped for a capacity of about 2,000 tires per day.

ROBSTOWN—The industrial department of the local Chamber of Commerce is considering the establishment of a new brick-manufacturing plant near the city. A company will be organized to operate the factory, or arrangements made with an existing brick manufacturing company to construct and operate the works. A fund to provide for the erection is being arranged.

SABINE—The Magnolia Oil Co. will rebuild the portion of its local plant, recently destroyed by fire, with loss estimated at close to $175,000.

West Virginia

NITRO—The Carrier Chemical Co., 604 Kanawha National Bank Bldg., Charleston, W. Va., has preliminary plans under way for the construction of a new plant at Nitro, for the manufacture of a number of chemicals and chemical byproducts. C. F. Carrier, Jr., is chemical engineer.

FALLING SPRING—The F. A. Jones Stone & Lime Co., Zanesville, O., F. A. Jones, president, has acquired a tract of limestone property in this vicinity, and plans for the initial development of over 35 acres of the site. A mill and other mechanical structures will be built.

Wisconsin

RACINE—S. C. Johnson & Son, manufacturer of waxes, polishes, etc., will commence the immediate construction of the superstructure of its new 4-story and basement plant addition on 16th St. J. Mander Matson, Robinson Bldg., is architect.

Canada

ST. JOHN, N. B.—The Nashwaak Pulp & Paper Co. has plans in progress for extensive additions and improvements in its local mills, to increase the capacity from about 60 to 80 tons of pulp a day, with corresponding advance in the paper making division of the works. The project will cost about $500,000, including equipment. The company is operated by officials of the Oxford Paper Co., 200 5th Ave., New York, and the Bryant Paper Co., Kalamazoo, Mich.; Hugh J. Chrisholm and Felix Pagenstacher are presidents of the respective companies in the order noted.

Capital Increases, Etc.

THE REFINERS' OIL CO., Dayton, O., has filed notice of increase in capital from $400,000 to $700,000.

THE SAVOY DRUG & CHEMICAL CO., 28 East Kinzie St., Chicago, Ill., has filed notice of increase in capital from $12,000 to $75,000.

THE WATAB PAPER CO., Sartell, Minn., is disposing of a bond issue of $1,250,000, the proceeds to be used in part for extensions, general expansions, etc. David E. Town is president.

THE CONTINENTAL RUBBER CO. OF NEW YORK, 120 Broadway, New York, N. Y., has filed notice of increase in capital from $50,000 to $370,000.

THE JAMES BOLAND RENDERING & FERTILIZER CO., Jackson, Mich., has filed notice of dissolution under state laws.

THE UNITED GLUE CO., Indianapolis, Ind., has filed notice of dissolution under state laws.

THE DIAMOND BRICK & TILE CO., Cleveland, O., has filed notice of increase in capital from $50,000 to $100,000.

THE VIRGINIA-CAROLINA CHEMICAL CO., Richmond, Va., has arranged for a bond issue of $12,500,000, the proceeds to be used for additions to working capital, expansion, etc. C. G. Wilson is president.

THE CHESAPEAKE PAPERBOARD CO., Baltimore, Md., has arranged for an increase of $150,000 in capital for proposed expansion.

THE LINCOLN MILLS, LLD., Merritton, Ont., manufacturer of paper products, has arranged for a bond issue of $1,000,000, the proceeds to be used for additions to working capital, general operations, expansion, etc.

Arthur H. Wood and S. Edward Murray, Jr., receivers for the EMPIRE TIRE & RUBBER CO., Trenton, N. J., will offer the plant and property of the company at a public sale to be held in September, the exact date to be soon decided.

W. R. Shaffer, Henry W. Brooks, Jr., and P. P. Nelson have been appointed receivers for the HALLTOWN PAPER BOARD CO., Halltown, W. Va.

New Companies

THE FIBER PRODUCTS CO., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture fiber specialties. The incorporators are Edward E. and Arthur F. Felsberg, and Cyrus H. Vail, 784 Broad St., Newark.

THE NEW ENGLAND BRASS MFG. CO., Danbury, Conn., has been incorporated with a capital of $12,000, to manufacture brass products. The incorporators are Frank Perlin, M. E. Krebs, and M. M. Quamruddin, 100 White St., Danbury.

THE SURE LIVE TRANSPLANTER CO., New York, N. Y., care of L. A. Safian, 291 Broadway, representative, has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are C. H. Donner, A. Abt and E. Schwab.

THE BURDSAL-BAXTER PAINT CO., Indianapolis, Ind., has been incorporated with a capital of $25,000, to manufacture paints, oils, etc. The incorporators are Oliver P. Ensley and Malcolm Baxter, both of Indianapolis.

THE OZARK OIL CO., Detroit, Mich., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated with a capital of $250,000, to manufacture petroleum products. The principal incorporator is H. M. Senter, Detroit.

THE BARKER-BRIGGS CHEMICAL CO., Louisville, Ky., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are Daniel Briggs, Rowland A. Barker and Herbert F. Boehl, all of Louisville.

THE ROYAL BRASS FOUNDRY CO., 39 New York Ave., Newark, N. J., has field notice of organization to manufacture brass, bronze and other metal castings. Gothar B. Elsner, 20 Beech St., heads the company.

THE SIMPSON LEATHER CO. INC., Boston, Mass., has been incorporated with a capital of $25,000, to manufacture leather products. Charles A. Simpson, Trenton St., Melrose, Mass., is president and treasurer.

THE MANATEE COUNTY FERTILIZER CO., Bradentown, Fla., has been incorporated with a capital of $25,000, to manufacture commercial fertilizer products. J. H. Humphries is president; I. T. Williams, vice-president; and H. O. Horner, secretary, all of Bradentown.

THE DELEVAN SMELTING & REFINING WORKS, INC., Brooklyn, N. Y., care of J. M. Cleary, 25 Henry St., Brooklyn, representative, has been incorporated with a capital of $100,000, to operate a metal smelting and refining plant. The incorporators are A., I., and S. X. Toorock.

THE DIXIE WAX PAPER CO., Dallas, Tex., has been incorporated with a capital of $20,000, to manufacture waxed and other papers. The incorporators are R. G. Smythe, J. Irwin and G. C. Embry, all of Dallas.

THE JOHN L. MORRIS OIL CO., Cuyahoga Falls, O., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated with a capital of $150,000, to manufacture oil products. The incorporators are L. E. James, John L. Morris and Maurice Betts.

THE NEW ERA MICA CO., Penland, N. C., has been incorporated with a capital of $10,000, to manufacture mica products. The incorporators are Paul Willis and John V. Cox, both of Penland.

THE UNITED STATES PAPER MFG. CORP., 543 Calvert Bldg., Baltimore, Md., has been incorporated with a capital of $3,000,000, to manufacture pulp and paper products. The incorporators are Johnston V. Best, Wendell D. Allen and Lewis C. Merryman.

THE HERCULES RUBBER PRODUCTS CORP., Brooklyn, N. Y., care of the United States Corporation Co., 65 Cedar St., New York, has been incorporated under Delaware laws, with a capital of $7,600,000, to manufacture rubber products. The incorporators are Paul M. Richards, and George W. Bryan, Brooklyn; and Winfield Clearwater, Rutherford, N. J.

CONLEY & STRAIGHT, INC., Providence, R. I., has been incorporated with a capital of 250 shares of stock, no par value, to operate a metal refining plant. The incorporators are John A. Straight, George W. Bugbee, and T. H. Conley, 50 Lillian Ave., Providence.

THE TALMAGE MFG. CO., 3825 Ogden Ave., Chicago, Ill., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are Maurice M. Talmage, I. Wineberg and Joseph Kampner.

THE COLUMBIA STEEL & TUBE CORP., New York, N. Y., has been incorporated with a capital of $25,000, to manufacture steel tubing, etc. The incorporators are H. Lipton, L. Bardi, and A. Wynehouse, care of Slade & Slade, 200 Broadway, New York, representatives.

THE INTERSTATE CHEMICAL FOUNDATION, INC., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., has been incorporated under state laws, with capital of $2,500,000, to manufacture chemicals and chemical byproducts.

THE SOL CASTING CO., Linden, N. J., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture iron, steel and other metal castings. The incorporators are Raymond F. Sturges, Joseph Oxman, and Henry Lipp, Linden. The last noted represents the company.

THE ECONOMY SOAP CO., Buffalo, N. Y., care of William O. Shields, Morgan Bldg., representative, has been incorporated with a capital of $15,000, to manufacture soaps and kindred products. The incorporators are J. F. Wagner and S. S. Knaier.

EL DORADO SPRINGS DEVELOPMENT CO., El Dorado, Mo., has been incorporated with a capital of $300,000, to manufacture zinc products. The incorporators are William True, A. B. Stricklett and M. A. O'Connor.

THE PURITAN OIL & REFINING CO., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., representative, has been incorporated under Delaware laws, with a capital of $10,000,000, to manufacture petroleum products.

E. J. TODD, INC., New Haven, Conn., has been incorporated with a capital of $50,000, to manufacture rubber products. The incorporators are Alonzo P. Adams, Great Barrington, Mass.; R. H. Cameron, Hamden, Conn.; and T. C. Hadden, 195 Church St., New Haven.

THE OHIO VALLEY SHALE OIL & DEVELOPMENT CO., Huntington, W. Va., has been incorporated with a capital of $150,000, to manufacture petroleum products. The incorporators are H. H. Brown, C. B. Hill and R. E. Petty.

HENRY SHAPNER, SONS & CO., INC., Springfield, Mass., has been incorporated with a capital of $125,000, to manufacture leather products. Henry Shapner is president, and Sidney Shapner, 149 Summer Ave., Springfield, treasurer.

Manufacturers' Catalogs

THE ALLIS-CHALMERS MANUFACTURING CO., Milwaukee, Wis., has issued two new bulletins. "Synchronous Motors" is the title of Bull. 1124, in which there are numerous illustrations of this type of motor suited to various industrial applications, and their use for belted, coupled or direct-connected service. Particular attention is called to the use of these motors for driving air compressors, motor generator sets, also their use for rubber mill drive, flour mill drive, ice-making and refrigerating machinery, paper-making machinery, and for driving mine fans, pumps, etc. Bulletin 1109 is on "Distribution Transformers" having ratings of 200 kva. and smaller, suitable for lighting and power purposes and of the oil immersed self-cooled outdoor type.

THE FULTON CO., Knoxville, Tenn., calls attention to its first general catalog on Sylphon Heating Specialties, in which are listed only those articles that relate to heating and temperature regulation.

THE ELECTRO-ALLOYS CO., Elyria, O., has just issued a pamphlet on ThermAlloy, high-temperature castings.

THE CONVEYORS CORP., Chicago, Ill., has issued an illustrated booklet entitled "Cut Ash Handling Costs," which should be of interest to the power plant executive. The booklet is an exposition of the steam jet conveyor method of ash handling and contains a description of the conveyor and its method of operation. It also gives a list of guarantees offered by the company, which include: Cost per ton of ash handled; cost of repairs per ton of ash handled; nonpacking of ashes in the ash storage tank; absence of dust at discharge and nonfreezing of ashes in the tank. Copies can be obtained on application.

THE SCIENTIFIC MATERIALS CO., Pittsburgh Pa., has published a special bulletin on the F and F Optical Pyrometer. The bulletin contains a discourse on the general theory of optical pyrometry, with a description of the F and F device and its practical industrial applications. This instrument is well adapted for use in determining temperatures at coke plants, ceramic plants, steel mills, iron furnaces and in other cases of high-temperature measurements where contact with the heated body cannot be made, where the position of the pyrometer must be distant from the heated object or where the temperature to be measured is above the range of thermocouple pyrometers.

THE CENTRAL SCIENTIFIC CO., Chicago, Ill., has issued Catalog R, which is a price list of chemicals and reagents, including Cenco certified chemicals and other standard makes of c.p. and U.S.P. chemicals, certified biological stains, certified rare sugars, culture media, indicators and commercial chemicals for general laboratory use.

THE SURFACE COMBUSTION CO., industrial furnace engineer and manufacturer, of 366 Gerard Ave., Bronx, New York City, is issuing a series of bulletins pertaining to industrial furnaces. Bulletin 3-D is devoted to Surface Combustion Low-Pressure Air-Gas Inspirators, which are readily applicable to any make of gas furnace. Bulletin 5 is entitled "Surface Combustion Oven Furnaces," and describes furnaces for the heat-treatment of both carbon and high-speed steel. Bulletin 6 is devoted to Surface Combustion Pot-Hardening Furnaces. Bulletin 7 is entitled "Surface Combustion Soft Metal Furnaces." Bulletin 8 is devoted to Surface Combustion Galvanizing Baths. Bulletin 16 is entitled "Surface Combustion Shipyard Furnaces." Bulletin 17 is about Surface Combustion Rivet Heaters. Bulletin 18 is entitled "Surface Combustion Small Forges." Bulletin 24 is entitled "Surface Combustion Laboratory Furnaces for High Temperatures."

THE COMBUSTION ENGINEERING CORP., New York, calls attention to a new booklet relative to its powdered coal installation at the River Rouge plant of the Ford Motor Co., which contains some interesting information on operating results at the plant, which has been in operation slightly over a year.

THE AMERICAN NICKEL CORP., Clearfield, Pa., is distributing a booklet, Bull. 101, on "Pure Malleable Nickel" giving a résumé of its properties and uses.

THE NORTHERN EQUIPMENT CO., Erie, Pa., has issued a booklet entitled "Regulating Boiler Feed Water." The subject has been treated in an entirely new way, the object being to cover the subject of boiler feed water regulation completely and yet very briefly. To accomplish this purpose, free use has been made of a graphical method of presentation, charts showing the effect of feed water temperature, etc.

THE HYDRAULIC PRESS MFG. CO., Mount Gilead, O., has recently issued two bulletins which have been got up especially to meet the demands of radio manufacturers for presses for forming and molding such materials as Condensite and Bakelite.

THE JEFFREY MFG. CO., Columbus, O., calls attention to Bulletin 369, dealing with the Jeffrey portable belt conveyor. This conveyor has been designed to meet a demand for a light inexpensive loader that would handle both bulk and package material. This bulletin illustrates and describes this machine. Two or more of the conveyors may be used together to extend storage pile, or the portable belt conveyor may be used as an extension conveyor to storage pile in connection with the Jeffrey portable car unloader. It can be operated by either electric motor or gasoline engine.

THE SHEPARD ELECTRIC CRANE & HOIST CO., Montour Falls, N. Y., has issued illustrated pamphlets on the Shepard Electric Liftabout; Bull. M-3, on Form IX Hoist With Geared Trolley From ½- to 20-Ton Capacity; Bull. M-4, on T-bar Insulator; Bull. M-5, Form 36W Back-Geared Motor Winch From 800- to 3,500-lb. Capacity; Bull. M-7, Form 23 Hoist With Geared Trolley From 1- to 6-Ton Capacity; Bull. M-8, Form 8 Hoist From ¼- to 6½-Ton Capacity, and a pamphlet on Hoisting Equipment for Ice Plants. This company has also issued a catalog illustrating and describing the Shepard Electric Hoist equipped with Zobell electric motor.

THE INTERNATIONAL NICKEL CO., New York, in Bull. 103 gives some of the uses of Monel metal in the textile industry, including bleaching and dyeing machinery, carpet, felt and hat making, centrifugals, extractors, dehydrators, tanks, warp mercerizing machinery, drying machinery, shaping clips, etc., on spinning machines, rolls and cylinders, carbonizing and scouring machinery, jack-spool heads, drying cans and textile pins.

THE HERCULES POWDER CO., Wilmington, Del., calls attention to a 56-page booklet illustrated with photographs and diagrams, entitled "Eliminating Waste in Blasting." It tells how some progressive companies are preventing waste in blasting, together with recommendations of the Hercules Co. In this book the company endeavors to give users of explosives the benefit of information gathered on the best methods for reducing blasting costs. They will be supplemented with bulletins from time to time. Copies will be sent to anyone interested, upon application to the Advertising Department, Hercules Powder Co., Wilmington, Del.

Coming Meetings and Events

ALPHA CHI SIGMA dinner, during the Chemical Exposition, will be held Thursday, Sept. 14, at 6:30 p.m. at Keen's Chop House, 107 West 44th St., New York City. Members are requested to register at *Chem. & Met.'s* booth at the Exposition.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition at Atlantic City, Oct. 23 to 28.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its 126th meeting at San Francisco, Calif., Sept. 25-29, 1922.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL SAFETY COUNCIL will hold its Eleventh Annual Safety Congress in Detroit, Aug. 28 to Sept. 1.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer, but will resume them in October.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a 3-day national convention in New York, beginning Oct. 18. The general topic of the convention is "Economics of Industry."

The President's Views On the Industrial Crisis

PEACEFUL and law-abiding citizens must have felt a bond of sympathy with the President as he recounted to Congress the story of his voluntary, but unsuccessful, efforts at mediation in the industrial crisis that faces the country. It is a record of patience under repeated rebuffs. If this were all, it would be disheartening; but there is ample evidence that the Chief Executive not only has his feet firmly on the ground but has his head high enough above the clamor and turmoil of industrial dispute to be able to see clearly and think straight on principles involved in the troublesome issues that treaten the nation. A strong advocate of respect for law and constituted authority, he logically seeks legal measures to insure the freedom and promote the peace and prosperity of the people.

Above all else President HARDING'S recent message to the Congress was a brief in the interest of the American people. Incidentally it did point the way to the only lasting solution of the coal problem and also pledged the powers of the government for maintaining transportation; but far transcending these matters in importance was the assurance that "no matter what hardships may attend or what sacrifice may be necessary, government by law must and will be sustained."

The President's demands for Congressional support and assistance are only those which an understanding people recognize as indispensable. There is no request for laws that will accelerate or force the settlement of present difficulties, for, wisely, the President is most concerned with righting a situation that will make their recurrence impossible. The message strikes at the very fundamentals of our trouble in the coal fields. Only by the elimination of evils that have led to the grossly excessive number of mines and miners can this industry be put on a sound economic basis. The fact-finding commission is the logical agency for attacking these basic problems. But this commission should, in our opinion, be vested with broadest powers, not only to investigate but to act and demand the necessary reformation and economic reorganization of the industry. The sooner this commission can function the better, for unless quickly forestalled further trouble is inevitable either next spring or at the expiration of whatever wage agreements are now to be effected.

With respect to the proposal of a "temporary national coal agency" to control the purchase and distribution of coal, there will be less accord. It is to be regarded only as a measure of final resort in case the operators are unable or unwilling to serve the public at a fair price. Fortunately the latter class is but a small proportion of the industry, which for the most part has loyally cooperated with the government.

In the opinion of those well informed on the subject the emergency would be passed before a commission of this kind could begin to function effectively. Developments immediately following a resumption of coal mining are likely to indicate whether or not a government agency of this kind is necessary.

It is hoped that present negotiations pointing toward a settlement of the rail strike will include some mutual agreement for observance and respect of the decisions of the Railroad Labor Board. Nevertheless the need for strengthening legislation has been clearly shown by the developments of the past year. When the Esch-Cummins law was enacted it was without precedent on the statute books and naturally after a considerable period of operation Congress may well consider a number of perfecting amendments.

In concluding his message the President laid down the broad principles on which the government purposes to act in putting an end to lawlessness and violence. For these principles we have nothing but commendation and approval. With him we thoroughly believe: "It is fundamental to all freedom that all men have unquestioned rights to lawful pursuits, to work and to live and choose their own lawful ways to happiness." Once this principle is universally recognized there will be no class domination nor will the public welfare be surrendered to a small minority that has the temerity to oppose the organized forces of law and order.

The Senate Raises Rates In the Chemical Schedule

DETAILS of the Senate's final action on the chemical schedule of the tariff will be found in the news pages of this issue. Our correspondent states that debate waxed warm at various stages in the consideration of the bill, with opponents and proponents lined up as they have been throughout the tariff debate.

The general result of the Senate's deliberations on coal-tar chemicals was a rejection of the proposed embargo and substitution of an amendment by Senator BURSUM offering higher rates on coal-tar intermediates, dyes and chemicals. Not only was the ad valorem rate on intermediates raised from 50 per cent to 75 per cent, but the fixed duty was increased from 7 cents per pound to 10½ cents. Similarly rates on coal-tar chemicals and dyes were increased from 60 per cent and 7 cents per pound to 90 per cent and 10½ cents per pound. This amendment, coupled with the provision for so-called flexibility in the rates to July 1, 1924, represents the limit of the Senate's protection of the chemical industry.

The bill will now go to conference, where an effort will be made to harmonize rates in the House and Senate bills. The outcome cannot be foretold, because the Senate has made radical modifications in the Fordney bill. There are, however, in both houses of Congress warm advocates and strong supporters of the chemical industry to whom we can look with confidence for a strong fight in support of protection.

A Naïve Confession

PROMINENTLY displayed on the front page of a metropolitan daily last Friday was a press dispatch from Chicago featuring a statement by the dean of the College of Liberal Arts in Northwestern University to the effect that henceforth married instructors will not be engaged in that institution unless they have independent means. It seems that although "salaries at Northwestern are as high as in any other university," the cost of living in Evanston is unusually high and the social demands are greater than in most university towns. The terrible consequence is that instructors are unable to live and support a family on their meager salaries of from $1,600 to $2,500. Hence their wives seek positions in the peaceful Chicago suburb in order to eke out the family budget. All of this induces worry and leads to such a distracted state of mind over debts and other little domestic problems that the instructor is unable to concentrate upon his work and his educational value suffers accordingly.

And all this is given out in a sober, academic statement, apparently without regard for the number and variety of jokes it contains. First, there is the naïve confession that Northwestern is not giving its married instructors even the "living wage" which is scorned by all well-informed and intelligent labor leaders. Next is the paradoxical reference to college instructors with independent means. Why be a college instructor at Northwestern or any other school if one has independent means? But the remedy proposed is still more unique. Dismiss married instructors altogether, rather than meet a patent obligation and keep happy, contented workers. Perhaps this simple expedient will not be immediately appreciated outside of the department of sociology and economics—but what a ghastly joke the whole thing is on a married instructor in that department!

Perhaps the new ruling at Northwestern does not apply in the departments of science and engineering, but wherever applied it must inevitably have the effect of lowering the quality of instruction through the employment of immature instructors. In business the married man is more likely to be regarded as an asset than a liability. It is recognized that he has not only assumed duties and obligations that make for stability but also that he has reached a state of maturity that implies greater ability. But not so in the College of Liberal Arts at Northwestern. Here one must have a wealthy wife or riches in his own right, although we hope that the new ban on married instructors will not apply in technical courses, where it is recognized that immature instructors should not be employed. One of the conclusions reached by the committee on chemical engineering education of the American Institute of Chemical Engineers was that graduate students should not be used as major instructors in chemical engineering, even in the freshman year.

If universities want quality in instruction, as in other lines of human endeavor, they must pay for it. Recently we ventured the opinion that colleges would have to compete with industry in order to hold on their faculties men of exceptional promise. It begins to look as though the humble instructor is in greater need of our solicitude. It is from the ranks of instructors that universities recruit their professors of high and low degree. Brilliant students, who give promise of an equally brilliant academic career, expect to travel the familiar route to a professorship via the humble instructor's job, meanwhile working for a higher degree and earning enough to live on. If the first step in this customary routine is made so unattractive that a man must be a bachelor in domestic affairs as well as one of arts or sciences, the range of candidates from which faculties are to be recruited is narrowed not only in quantity but in quality also. Educational institutions generally must wake up to the necessity of competing for men on a business basis.

Wanted—Competition In the Coal Industry

IN OUR ISSUE of April 12, 1922, we pointed out that the waste in the coal-mining industry due to idle labor and idle capital is much greater than the waste in mining methods, about which so much has been said in the plea that we should think of posterity. It is only lately, through the prompting of the greatest strike in the history of the bituminous coal industry, that much has been said about the waste of workmen's time and of capital.

Now the subject is really up. F. S. PEABODY, a prominent coal operator and member of the A.I.M.E., uses particularly plain language in expressing the thought that is prominent in the minds of many men —that what is wanted is competition in the coal industry. Mr. PEABODY says there must be a weeding out of coal mines by competition, leaving the fittest to survive and work practically full time. He takes the conservative basis that the developed capacity is fully one-third greater than any possible demand, sets the excess capital at $400,000,000, the excess in miners at 200,000 and the excess cost of all this at $400,000,000 a year, 80 cents per ton of coal, which the country is paying in an excess coal bill.

The question is how to produce competition. It is a question that has never been up in a large way. Experience in human affairs shows that as a general rule there is a strong tendency for competition to arise, while men are disposed to devise artificial means to restrict competition. Hence we have been more or less busy with the problem of preventing the stifling of competition. We have the common law, converted into precise form by the Sherman law of 1890, and lately we have had the Clayton and Trade Commission acts.

Our general policy has been that if we prevent the restriction of competition we do enough. The question now is whether this policy is wrong or we have overlooked something in endeavoring to carry it out. Studying the history of the coal industry in the past quarter century or more, we find little suggestion that the familiar methods of trade restraint have been practiced, and we find furthermore that it would be particularly difficult to operate a price agreement in coal. There are many operators, of various sizes, and they are plainly difficult if not impossible to "control." Then there is the nature of the business, coal-mining districts being scattered over a large part of the country, each with its tributary consuming territory, and each with its own price.

Nevertheless, the plain fact is that competition, as a means of keeping prices down to a fair average level, has failed in the case of coal. The reason is conspicuous and simple. Our law forbids coal operators as well as other producers of commodities to agree with

one another to restrict production. The law does not forbid the coal operators to disagree with the United Mine Workers. Thereupon the United Mine Workers go on strike, and sometimes even close non-union mines, as they did this time in the Connellsville and some other districts.

It is seldom that the answer to a great problem is in advance narrowed down so precisely. It may be difficult of execution, but its general character is predetermined. The study must be prompt and vigorous, for while there have been biennial scales in the bituminous coal industry in the past, the recent "settlement" of the United Mine Workers runs only to April 1, 1923, seven months hence.

On Casting Steel, Copper And Other Things

MANY a foundryman will contend that the hardest casting to run in gray iron is not an intricate thing like a valve body, but a simple straight round bar. Many an argument has arisen over the proper way to mold it, and where the gates and risers ought to be. How to produce sound, perfect castings of this shape seems never to be settled to everybody's satisfaction.

Those same questions constantly confront the caster of ingots or slabs. He continually must make bars of solid metal in unexceptionable surface condition, especially when they are to be rolled into thin sheets. Furthermore, such is the kinship among metals that the precautions necessary for casting fine steels, so ably described by Colonel BARBA before the Mining Engineers last winter, are paralleled in non-ferrous practice.

To illustrate, consider the pouring of a long round "billet" of copper, to be pierced and worked into seamless tubing or bands. Assume that delicate furnace refining has put the metal into the exact "pitch" to solidify with a flat surface. A laborer dips a big ladleful from the bath, keeping some of the glowing charcoal floating on top to prevent oxidation of the metal en route, and trundles his load to the molds. Each one of these consists of a series of copper rings bored to a mirror finish and machined at the grooved joints; the lowest section has a pouring gate entering the bottom. A second workman empties a small hand ladle through this runner, and when the metal wells up, covering the bottom of the mold, the bull-ladle starts pouring from the top. In this manner all splashing is prevented. As the first section fills, the next ring is placed in position smartly, the ladle of hot copper meanwhile being raised by chain block, and pouring is resumed with the slightest delay. For such practice, the copper of course must be hot, so that fresh metal strikes a liquid pool and the stop-pour causes not the slightest defect. And so on until the 4-ft. bar is completed.

By the time the first section is poured the metal in the small gate is chilled, and by the end of the pour the billet is solidified possibly for half its length. The mass of the mold sections is most carefully adjusted for this rapid chilling effect; indeed the rate of solidification is balanced against the temperature of the metal, the temperature of the mold, the pouring rate and the "pitch" or gas content in the bath. It is therefore only the matter of a minute before the billet freezes with a flat top and without internal cavities or pipe of any sort. The molds are lifted straight up, section by section, off the red hot bar, and the lowest one opens on a parting. After partly cooling in water, they are slushed with bone-black, and are ready for another pour.

Here are seen the essentials of correct ingot pouring: Most carefully refined metal; correct temperature of metal and mold; the surface of the mold perfection indeed; absolute prevention of splashing, close control of pouring rate; quick stripping of molds. These things attended to, no difficulty is had in producing as a matter of course ingots of this shape—undoubtedly the most difficult yet devised to worry the caster—and of a quality so excellent that most exacting specifications covering the interior and exterior surface of tubing can be met with ease.

Illustrations need not be multiplied. This one perhaps suffices to convince that melters of copper, brass, bronze and aluminum could profit equally with steel makers from a study of the principles set forth on page 350, so ably enunciated by Colonel BARBA and the lamented Dr. HOWE.

Prehensility— Comprenez Vous?

WE REFERRED the word to one of our colleagues, who said he thought it must be the property of having a long and waving tail. We informed him that he was wrong, whereupon he said that it must be the property of having a short straight one.

It is neither. In fact it is a term applied to adsorbents in producing high vacua. It is the conception of seizing hold of the gas molecules rather than retaining them. It is greatest with plum-stone charcoal and less with birch charcoal, coconut charcoal, German charcoal, etc. Mathematically it is the slope of a curve about which the reader can discover more details by referring to the *Proceedings* of the Royal Society of Edinburgh.

The word, however, will serve admirably as a text. It represents a tendency—and not a healthy one—which may perhaps be described as the desire to coin a vocabulary. Of course, a definite and specialized vocabulary is necessary in chemistry and physics to express and co-ordinate the knowledge which those sciences have given us. And yet we feel that too little care and thought have been given to the niceties of language and the demands of good literature. In the case of "prehensility" the word is so definitely associated with the ability of monkeys to seize an object with their tails that it seems grotesque to develop a new application with reference to adsorbents. Language is already too complex, and words are too lightly added to an already overextended vocabulary. In fact, if we were not protesting against the practice, we might offer a dissertation on "nomenitis," the disease of naming things.

According to MARK TWAIN, NOAH had a simpler and more logical method which he applied when he was called upon to name the animals. As they passed in review he named them according to their appearance. Thus the lion looked so much like a lion that there seemed to be no chance of naming it anything else; and the giraffe—who could mistake that long neck and peculiar shaped body? It must be a giraffe, no other name would fit. And so on through the whole list. There is much to commend in the simplicity of NOAH'S system. Try it in the case of "prehensility" and see if you can visualize an adsorbent wrapping its tail firmly around a gas molecule, seizing it beyond the possibility of escape!

Readers' Views and Comments

Acid-Proof Material for Arsenic Acid Manufacture

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to my contribution in your issue of July 26 on "Calcium Arsenate Manufacture," which on account of haste I did not see in proof before publication, my attention has been called to one slight inaccuracy which requires notice.

In the description of acid-proof material used for arsenic acid manufacture my article as written referred to Duriron, as this is the only alloy, to my knowledge, which has been successfully used for the apparatus described. Your editor in changing the wording (I assume to eliminate from a technical article reference to a commercial name) substituted for the word "Duriron" the words "high-silica iron." This phrase is not correct according to my understanding, as Duriron is properly termed a "high-silicon iron" or a "ferro-silicon."

The alloy was referred to in this article not in any broad or generally descriptive sense, but to indicate definitely the material already proved suitable for a requirement permitting radical improvement in the production of this acid. To my own knowledge costly failures have resulted from efforts to use other kinds of iron kettles for this particular purpose and I would naturally prefer not to appear to write authoritatively on the subject with such phraseology as might be misconstrued.

With the desire for accuracy which I know you have and which from my personal standpoint is equally desirable I am suggesting this correction.

New York City. H. W. AMBRUSTER.

Dezincification of Brass

To the Editor of Chemical & Metallurgical Engineering

SIR:—I should like to take issue with the investigators of the Corrosion Committee of the British Institute of Metals[1] upon their conclusion that true dezincification of brass never occurs. Microscopic examination of dezincified samples of Admiralty alloy submitted to me indicates very clearly that zinc has been removed and the copper left in place. Spongy, brittle copper remains, occupying exactly the same space and position, and in every way apparently exactly what should be left, provided the zinc had been dissolved out of the brass. Small particles of brass are frequently found in this mass in the form of crystals or islands of the original metal. I have seen corroded tubes where copper has apparently been re-deposited, but the experience of the American Brass Co. with condenser tubes does not lead us to think that this can be anything but a very extraordinary case resulting from abnormal conditions of exposure.

We very seldom find tubes in the same condenser differing in the character or amount of adhering deposit. In some condensers the tubes have a very hard, one might say "stony," deposit. Such tubes have lasted for a long period in sea water service. On the other hand, where condenser tubes fail in a very short time they generally do not possess such a deposit. The deposit is either partly wanting or is very soft and apparently slimy when wet, and after being dried out it has not the continuous enamel-like appearance referred to.

Waterbury, Conn. W. H. BASSETT.

A New Vessel for the Absorption of Hydrochloric Acid

To the Editor of Chemical & Metallurgical Engineering

SIR:—Under the above title in your issue of Aug. 2 Stephen L. Tyler states that "The tower has been used extensively for the absorption of hydrochloric acid gas, but from this it is possible to produce only acids of low strength, as it is not practicable to construct absorption towers with sufficient cooling to keep the tower temperature down to a point where high strength acid may be produced."

In my report on the operation of the plant at Emporium in *Chem. & Met.*, Nov. 2, 1921, page 834, it is shown that 20 deg. Bé. acid is regularly produced without the use of any absorption apparatus but towers and from gases running as low as 3 per cent HCl. The necessary cooling is obtained by circulating a large volume of acid with pulsometers. M. A. LAURY.

Rockville Center, L. I.

To the Editor of Chemical & Metallurgical Engineering

SIR:—In my article on "A New Absorption Vessel for Hydrochloric Acid" which appeared in your Aug. 2 issue a number "1" is omitted from Fig. 4. It should be placed opposite the upper layer of air-cooled coils. It is referred to in the text and without it there might conceivably be some confusion. I would appreciate your calling this to the attention of your readers.

New York City. S. L. TYLER.

The Technology of the Carbon-Electrode Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—The fourth article of the series on "The Technology of the Carbon-Electrode Industry" contains two rather unfortunate errors of typography, the effect of which, in one case at least, is entirely to reverse the writer's original meaning. Thus on page 259, under the heading "Comparison of Molding and Extrusion," the word "not" has crept into the fourth paragraph and should, of course, be omitted. The paragraph would then read: "In the case of large electrothermal electrodes, the high density and low resistivity of the electrode are as important as when smaller currents are used."

Again on page 260 it would seem that the captions for the illustrations had been reversed. The press shown in the cut on the right has a capacity of 750 tons and not 350 tons. It is obvious, I believe, that the comparative sizes of the presses do not agree with the capacities which you have indicated.

I shall be obliged to you if these corrections are brought to the attention of your readers.

Brooklyn, N. Y. CHARLES L. MANTELL.

Ido, the Universal Language

To the Editor of Chemical & Metallurgical Engineering

Sir:—As a subscriber for *Chem. & Met.* I take the liberty of presenting one reader's views and comments on the synthetic language Ido.

Ido

(How is it pronounced?)

There once was a pup dog named Fido
Who became quite proficient in Ido,
For German and French
Gave his tongue such a wrench
As to force him to cut quite a dido.

His master, a likeable kiddo,
When of age fell in love with a widow.
Though she came from far Burma,
Their love was the firmer
Because they could say it in Ido.

In movies the next thing that he do
Is to come to a clinch just like she do.
'Twas a suitable match
For they came to the scratch,
And whispered soft nothings in Ido.

Her father, whose wealth was his credo,
Soon asked of the young man had he dough.
"I've houses and land,
And coin plenty as sand,"
He answered quite glibly in Ido.

Washington, D. C. C. E. WATERS.

The Chemical Industry in Chile

FROM OUR SANTIAGO CORRESPONDENT

SANTIAGO, CHILE, AUG. 1, 1922.

CHILE has developed a flourishing industry by means of obtaining and preparing chemicals in their original state which are especially intended for the export trade. The names of these products, with the amounts produced during the past 3 years, are given in the following table:

	1918	1919	1920
Sodium nitrate, metric tons	2,875,902	1,703,240	2,523,458
Iodine, kg	1,078,760	243,167	350,066
Calcium borate, metric tons	6,603	10,116	15,823
Sulphur, tons	19,557	18,910	13,340
Perchloride of potassium, kg	118,327	20,696	33,487
Sodium sulphate, metric tons	1,220	.....	.....
Sodium chloride, metric tons	54,536	29,454	33,951

During 1921 interesting deposits of sodium carbonate were discovered, 50 per cent pure, the remainder being mostly moisture and organic matter. The extraction of these products is destined to develop an extensive industry, as the deposits are important and the transportation lines now under construction will permit of the products being moved with ease for shipment to foreign markets.

MANUFACTURE OF CHEMICAL PRODUCTS

The manufacture of chemical products has had a slow development in Chile owing principally to the small consumption, the variety of products which are needed in the work and the difficulty of transportation due to the configuration of the country. The manufacture of sulphuric acid, which is a vital industry, has not thrived. A premium of $0.05 (Chilean gold) per kilo of 66 deg. acid was allowed and a factory was opened in Guayacan, Coquimbo, using the contact process, but it shut down as soon as the payment of the premium was withdrawn. At present there are several factories producing sulphuric acid by the chamber process. Of these, two are operated solely for the purpose of supplying the mining camps of Teniente and Chuquicamata, which depend on them for their supply of sulphuric acid, and three to supply the public demand. In almost all of these factories, with the exception of Teniente mine, native sulphur is used. Chamber acid and 66 deg. acid are the only forms produced at present, no fuming ever having been made. Hydrochlorate and nitric acid for commercial use are also manufactured. Small quantities of acetic acid are manufactured, notwithstanding the fact that sodium acetate is exported.

In the line of basic chemistry, development has been confined to the crystallization of sodium carbonate. In the nitrate regions an impure sodium carbonate, called "natron," is produced by burning nitrate with carbon. This is used for the manufacture of solutions of bisulphite used to extract iodine.

The deposits of sodium sulphate in the northern part of the country and the consumption of caustic soda and salts there would serve as an economic basis for establishing a factory to produce Leblanc carbonate in Antofagasta and its environs.

Among the ordinary chemical products locally manufactured are boric acid, iodide of potassium and sodium, nitrate of silver, sulphate of copper, iron and aluminum, refined cream of tartar, ordinary ether, glycerine, compressed oxygen and carbon dioxide, naphtha and other products of minor importance.

The wood-distillation industry is still in its infancy, several small factories having been established which produce methylene and calcium acetate. There is a large factory which produces tannic extracts, using the bark of the elm tree, and also a factory producing paste for mechanical purposes, using the bark of the *Araucaria imbricata.*

There are five factories producing illuminating gas, two of them having tar distilleries, although they only separate the raw products without crushing or refining them.

There are several oil factories producing olive, castor, cottonseed, linseed and other similar oils. Industries utilizing fats are only beginning to be built and the manufacture of soap is carried on along very primitive lines. There are some plants for the recovery of glycerine.

The manufacture of all kinds of fermented products is conducted on a large scale, excellent wines and beers being made, and alcohol is produced in greater quantity than that needed to supply the requirements of the country. There are several small starch and gluten factories. The tanning and allied industries are very much developed, local material being used from which a very good grade of hides is produced.

The Record in Pulverized Coal Installations

Chemical engineers have followed the extensions in the use of pulverized coal for fuel with much interest. Combustion is primarily the province of the chemical engineer and the extension of improved combustion methods affects him in many ways.

In this connection it is worth while to note the equipment which is to be used in the Cahokia Station of the Union Electric Light & Power Co., St. Louis, Mo. This plant, an eventual 240,000-hp. development, will raise steam with B. & W. boilers fired by the "Lupulco System" of pulverized coal burning, installed by the Combustion Engineering Co. The coal will be powdered in a battery of ten Raymond Six-Roller Low-Side Mills. This pulverizer installation will comprise, so far as can be ascertained, the largest single coal pulverizing installation so far made for any purpose whatever.

What's in a Name?

The Moot Question, Does the Trademark Belong to and Protect the Business or Does It Protect the Consumer? Is Discussed and Illustrated by Recent Celebrated Cases—The Effect of This Point on Commercial Transactions Between Americans and Foreign Corporations

By Wellington Gustin
Of the Chicago Bar

THE rights carried by a trademark covering one's products appear to be not very definitely defined in the rules of law, nor settled by decisions of the courts. "What's in a name?" in a business sense is of grave concern to business from more than one angle. Is a trademark and trade name something to be protected by the laws for the benefit of its claimant or for the benefit of the public? Is it a right or property for the protection of the business and products of private individuals, or is it a right to be enforced by the laws and rules of equity for the prevention of frauds upon the public? Some recent cases in the federal courts show a state of uncertainty as to these matters.

The Purchase of Exclusive Rights to Foreign Trademarks

The question chiefly involved in this article concerns the importation and sale in the United States of products manufactured under a trade name or mark in a foreign country, where the manufacturer has sold his rights to the name or mark in this country. Under one line of decisions the tendency is to permit an importer to sell foreign trademarked goods in this country, though an American firm may have purchased and owns the trademark rights in this country, provided, of course, the importer has purchased the products from others than the manufacturer. The proposition has not been passed on by the United States Supreme Court, and there are other points of law connected with the rights to a trademark not yet settled. The importance of the subject is obvious, when we remember the chemical products and their trade names of German manufacture sold to American interests during the late war.

The Java Poudre Case

A case now pending in the United States Supreme Court on a writ of certiorari to the United States Circuit Court of Appeals for the Second Circuit concerning trademark rights and unfair competition is of great importance to all users of trademarks and trade names, A. Bourjois & Co., Inc., vs. Anna Katzel (42 Sup. Ct., 92).

A. Bourjois & Co., Inc., a New York corporation, brought suit for an injunction against Anna Katzel. The company is the exclusive owner of certain registered trademarks for face powder, these trademarks consisting of the word "Java" and the various labels which are carried by its boxes and serve to identify them as its products. Anna Katzel's boxes are, with two differences, exact duplicates of plaintiff's boxes.

In 1912 the firm of E. Wertheimer & Cie. of France, successors of A. Bourjois & Cie., also of France, had established in the United States the business in Java face powder in boxes under labels substantially the same as those in controversy. The plaintiff New York corporation, mentioned above, was organized in 1913, and for a consideration involving, *inter alia*, the obligation to pay $400,000, bought the entire business then and theretofore carried on by A. Bourjois & Cie., E. Wertheimer & Cie., successors, in the United States—namely, the entire good will of said business in the United States, and any and all trademarks, trade names and trademark rights relating thereto in the United States, and also the sole and exclusive right to manufacture and sell in the United States any and all toilet preparations then or theretofore made by the French concern. This transfer of trademarks included the transfer of the registered trademark "Java," the top and other labels of the boxes, and all of the trademarks which the plaintiff had subsequently used and registered. Thus, the District Court says, all of these trademarks and labels are, so far as the United States is concerned, exclusively the property of the New York corporation.

Promotion and Development of Market

It appeared that the company in suit has expended substantial sums of money for advertising and has created a wide market in the United States for its products, building up not only an extensive and important business, but also an excellent business reputation for the character of its products, and that it depends in greatest measure upon its trademarks to prevent invasion of its rights.

Plaintiff buys the powder in bulk from the French firm, A. Bourjois & Cie., and then puts up this powder in the boxes containing the trademark inscription. The District Court says, however, that plaintiff may buy its powder from any house, and will obviously do a favorable business in connection with its trademarks, so long as it satisfies the public, which it has done in the past. Two outstanding features of its packages consist of the words "Poudre Java" and "A. Bourjois & Cie."

Defendant Imports the Same Material

The facts further showed that the package sold by the defendant, Anna Katzel, was the genuine box or package of the French firm of A. Bourjois & Cie., and that defendant had bought abroad the products contained in the genuine packages and same were imported into this country.

On the back of plaintiff's box or package are the following words: "Trademarks Reg. U. S. Pat. Off. Made in France—Packed in the U. S. A. By A. Bourjois & Co., Inc., of New York, Succ'rs in the U. S. to A. Bourjois & Cie. and E. Wertheimer & Cie."

As the defendant's box or package is manufactured and sold in France, the words just quoted do not appear upon it. It was urged by defendant that plaintiff's product is a misrepresentation and in the nature of a fraud upon the public, in that it gives the impression that it is manufactured and put up in the original packages in France. But the court found that

the public had full notice of the facts due to the quotation above on plaintiff's packages.

From the above facts the United States District Court regarded the important question in the case to be whether, because defendant's package is a genuine article made and sold by the French concern, it can be said to constitute an infringement of the trademarks of plaintiff, when plaintiff is the exclusive owner of these trademarks in the United States.

The court points out that a trademark has come to be recognized as a property right of immense and incalculable value, and that the proprietor of a trademark by virtue of the manufacture or offering for sale of his goods is entitled to the protection which the highest powers of the court can afford.

In another case the Supreme Court of the United States holds that redress is based upon the party's right to be protected in the good will of the trade or business and the English rule that a trademark is not the subject of property, except in connection with an existing business, prevails in the United States. However, the court has held in Scandinavia Belting Co. vs. Asbestos & Rubber Works (169 C. C. A., 87) that the owner of a registered trademark can restrain its use by another, though no loss of sales is shown and though there may be no fraud between the original seller and buyer of the infringing article.

Judge Mayer's Able Opinion Supported Plaintiff

The District Court found that defendant's trademarks was genuine, in the sense that it was not spurious at the place of origin, and that no change has been made since it was sold; but it says it is genuine as matter of law only if defendant has the right to sell within the territory where plaintiff is the exclusive owner of the trademark, and also where plaintiff has established a business in the product in connection with the trademark.

The court further found that plaintiff has expended a large sum for the acquisition of the trademark title and rights and for the advertisement of its business. Further it had corralled the American market before defendant's boxes were brought into this market. If now, says the court, the original French boxes or packages can lawfully be permitted to compete with plaintiff's boxes and packages, it is seen that plaintiff's business may be destroyed, and in any event impaired.

The question, says the court, is one involving business interests in a large way. If an American business concern buys all the rights of a business established here by a foreign concern, and then the foreign concern is nevertheless at liberty to compete with the American concern, the result will be that the purchase of rights, under such circumstances, will give little or no protection, and the foreign concern as well as the domestic concern will be seriously injured in the long run, because American capital certainly will not be invested, and foreign concerns will find it difficult to sell the rights which they have developed in this country.

Defendent Believed She Was Within Her Rights

The court says in justice to A. Bourjois & Cie. of France that nothing in the record of the court proceedings would justify the conclusion that this competition has been undertaken with their knowledge or consent, and in justice to defendant that she has relied upon what she regarded her legal rights. The question is one of law which calls for definite and prompt settlement.

In support of her position in importing the original article and selling it, the defendant cited the case of Fred Gretsch Manufacturing Co. vs. Schoening et al., 238 Fed., 780. But the trial court in the case at bar shows that case involved a construction of section 27 of the act of Feb. 20, 1905 (Compiled Stat., section 9513). This section was in the nature of a customs regulation, to prevent the American public from being deceived by simulated name. Simulated trademarks were to be excluded from importation, so as to safeguard the American public. Under this law the customs authorities may only exclude an article "of imported merchandise which shall copy or simulate the name of any domestic manufacture. . . ."

Not a Question of Genuineness of the Article

Thus, says the court, if an article is genuine, in the sense of defendant's box, it may be imported into this country and cannot be stopped at the door of the custom house; but whether the article may be marketed here under a particular trademark is a question to be determined in ascertaining the rights of parties, quite irrespective of section 27. Section 27 concerns the action of the government, through its proper officials, in carrying out the safeguarding measures erected by Congress. The case at bar concerns the rights of private parties, and those rights depend wholly upon different rules of law. Therefore, in this case, wherein the original owner of the business and its trademarks had completely parted therewith to a vendee, who had proceeded upon the strength of his ownership to develop an American market, the court was of opinion that plaintiff is entitled to have defendant's product excluded from the American market and so granted an injunction to plaintiff.

Circuit Court of Appeals Reversed the Decree, 2 to 1

Despite this well-reasoned opinion by District Judge Mayer of the Southern District of New York the United States Circuit Court of Appeals has reversed the decree, in an opinion handed down by Judges Ward and Manton, but with Judge Hough dissenting.

Analogy to Hunyadi Janos Case

In this opinion the Court of Appeals assumes that it would be a breach of the French firm's obligations to the New York corporation to sell its face powder in the United States. Its products are imported and sold, however, by defendant herein. The question, as this court saw it, is whether the defendant has not the right to sell this article under the trademark which truly indicates its origin. And it decides that she has this right. It supports this view by the case of Apollinaris Co. vs. Scherer, 27 Fed., 18. Here the proprietor of the Hunyadi Janos spring in Hungary gave to the Apollinaris Co. the exclusive right to sell the water under the trademark "Hunyadi Janos" in the United States. The Apollinaris Co. registered the name and labels as trademarks in the United States Patent Office. Scherer applied to the proprietor, Saxlehner, to sell him the water for importation into the United States, which Saxlehner refused to do because of the granting of such exclusive rights to the Apollinaris Co. Thereafter Scherer purchased the

water from other parties in Germany, imported it into the United States and sold it under the name Hunyadi Janos and with the same label as the Apollinaris Co.'s. Herein the court says the defendant was selling the genuine water, and therefore the trademark is not infringed. There is no exclusive right to the use of a name or symbol or emblematic device except to denote the authenticity of the article with which it has become identified by association. The name has no office except to vouch for the genuineness of the thing which it distinguishes from all counterfeits; and until it is sought to be used as a false token to denote that the product or commodity to which it is applied is the product which it properly authenticates, the law of trademarks cannot be invoked.

Le Page's Glue Also Quoted

The Court of Appeals cited another case, Russian Cement Co. vs. Frauenhar, 66 C. C. A., 500. Here the defendant bought in bulk of third parties glue made and sold by the plaintiff under the trade name of Le Page's Glue and bottled and sold same under that name. The labels on defendant's bottles contained no statement as to whether the glue put up by it was either of a superior or inferior quality, but merely that this glue was manufactured by the plaintiff and bottled by defendants. The complainant urged that this was a fraud upon the public and that defendants should be enjoined from applying the name "Le Page" to a glue, though made by itself, which is inferior to the most expensive brands sold by complainant under that name. The court here said that if the public does get an inferior quality of glue when it purchases that bottled by defendants, it is because the complainant itself has seen fit to sell such glue under the same trade name as it had applied to a superior article. In the absence of an attempted fraud a court of equity will not enjoin a person from affixing to goods sold by him their true name and description. Here the label tells the truth and nothing but the truth, says the court. There is no fraud upon the public, for it gets the genuine, identical thing described by the label; and there is no fraud upon the manufacturer, for its vendees resell its manufacture, to which it has applied its name, coupled with the statement that it (the vendee) is responsible for the manufacture.

Eternelle Violin Strings

In another case the Gretsch Co. had the exclusive agency for the United States of the sale of violin strings made in Germany by Mueller under the name "Eternelle," and with Mueller's approval registered the name as the trademark in the U. S. Patent Office. Schoening purchased such strings in Germany and imported them into the United States. The case arose under section 27 of the trademark act (Comp. Stat., section 9513) as to the importation of merchandise copying or simulating a trademark registered in the U. S. Patent Office. Here the court says, "Assuming that Congress could protect the owner of a registered trademark against the importation by third parties of the genuine article under that trademark, has it done so? We think not. The act prohibits the entry of imported merchandise which shall 'copy or simulate' a trademark registered under it. The obvious purpose is to protect the public and to prevent any one from importing goods identified by their registered trademark which are not genuine. In this case, however, the imported goods were the genuine articles identified by the trademark."

But Trademark Is Not a Patent and Should Only Protect the Public

Returning to the case of Bourjois & Cie. vs. Katzel, the Court of Appeals points out that the analogy between patents and trademarks is not complete. A patent gives a patentee a monopoly to make, sell and use and grant to others the right to make, sell and use the subject patented in the United States for the term of the patent. Hence articles lawfully made, used and sold in foreign countries cannot be sold in this country if they infringe the patent. Trademarks, the court says, are intended to show without any time limit the origin of the goods they mark, so that the owner and the public may both be protected against the sale of one man's goods as the goods of another man. If the goods sold are the genuine goods covered by the trademark, the rights of the owner of the trademark are not infringed.

Judge Hough, Dissenting, Holds Trademark Primarily Protects Business

In his dissenting opinion Judge Hough points out that the proposition "whether a trademark is to be primarily regarded as protecting the trademark owner's business from a species of unfair competition, or protecting the public from imitations," is not yet settled. He thinks the decision in this case leans the wrong way, because it is his opinion that a trademark is primarily a protection to the owner's business.

Continuing, he says that if the primary function of the trademark is to protect this plaintiff's business in his own country, it makes no difference at all that the genuine French article is the thing offered by defendant. That genuine article has become an infringement because the business of dealing in that article within the United States is the plaintiff's business.

Thus there are two federal Circuit Judges holding one way and one federal Circuit Judge and one federal District Judge holding another in this case.

Referred Now to Supreme Court

On a petition for a rehearing the Circuit Court of Appeals denied the petition. This court was asked to certify the question involved to the United States Supreme Court on the ground of its supreme importance in view of the many businesses with their accompanying trademarks of German citizens, bought during the European war by citizens of this country from the Alien Property Custodian. On this occasion the court says it is not doubted that an American citizen may buy the business of a foreigner in the United States, with its accompanying trademarks, and, having done so, may subsequently change the character and quality of the goods at pleasure.

The decisions on one side would open competition in the sale of the trademarked products, a thing usually accorded for the benefit of the public generally; the decision on the other side would tend to create a legal monopoly, a thing abhorrent to the general policy of law. Yet the latter view would tend to greater stabilization of business, in giving certainty to the rights and to the values in marks and names purchased from foreign manufacturers.

Industrial Alcohol for the Chemical Engineer

By James M. Doran

ad, Industrial Alcohol and Chemical Division, Prohibition Unit, Bureau of Internal Revenue

HE chemical engineer or factory superintendent working on a new process or perfecting an old e frequently finds that he needs alcohol for some irpose. It may be that he has been using benzene, her or acetone as a solvent and finds for reasons of onomy, such as minimizing factory losses, obtaining greater degree of purity or a finer appearance of the oduct being manufactured, that alcohol will serve s purpose better than other solvents. It may be that preparing some new organic compound, such as a dye a pharmaceutical, alcohol is necessary in order to oduce and place upon the market the product in commercially paying quantity. Again, the production of me new ethyl ester may open up a new field of profit r the chemical manufacturer.

"How Can I Get Alcohol?"

In all of these contingencies and countless others e question at once arises: "How can I get alcohol? there not a high tax on it and does not the national ohibition act make it difficult to obtain without a lot expense, red tape and endless trouble?" An inquiry made possibly from some associate or business quaintance who uses industrial alcohol and in due urse of time a copy of the internal revenue regulations obtained and read over. It looks formidable; maybe would mean trouble and worry and perhaps not be good business venture. This is not an unusual experice and in this short article an attempt will be made explain in as simple terms as possible the operation the present industrial tax-free alcohol laws as they fect the industrial chemist.

Alcohol, pure or denatured, is the subject of tax laws d governmental regulations in practically every vilized country. The United States in many respects ads other countries in its liberal industrial alcohol ws. Congress has consistently favored and encourged the use of tax-free industrial alcohol through naturation provisions from the first denatured alcohol t of June, 1906, down through the national prohibion act now in effect. Under this last-named act the dustries of the country using denatured alcohol are nply provided for. In so far as the user of denatured cohol is concerned, the present regulations drawn nder the national prohibition act undoubtedly provide r a more liberal encouragement of industry than gulations in effect before the Eighteenth Amendment came operative. It is safe to say that the attitude the officials of the Internal Revenue Bureau who dminister the national prohibition act was never more iendly to industrial alcohol honestly and legitimately ed than at present. So, generally speaking, there no more red tape, burden or trouble imposed upon the er of alcohol in this country than in any other coun-y. The same governmental regulations are in effect ractically everywhere and there is no handicap in that gard peculiar to the United States manufacturer.

Denaturation of alcohol is accomplished generally at e place of manufacture under the supervision of inrnal revenue officers and in addition the denaturants used are of specified quality and in most cases tested by an authorized chemist before use. Broadly speaking, there are two classes of denatured alcohol: completely denatured alcohol and specially denatured alcohol.

Completely Denatured Alcohol

There are six authorized formulas for completely denatured alcohol. The denaturants used are wood alcohol, benzene, pyridine, kerosene, ether, gasoline, nitrobenzene and orthonitrotoluene. In each of these six formulas there are combinations of one or more of the above denaturants that impart odor and taste and, in addition, make a recovery of potable alcohol from the mixture extremely difficult. The six formulas offer a rather wide range of choice and can be purchased without permit or bond. They are useful for many technical solvent purposes where the added denaturants offer no serious chemical or physical objections. The chief uses are: Fuels; anti-freezing solutions; cleaners; certain grades of shellacs, varnishes and paints; and technical purification processes.

The only restrictions on the use of these formulas are that they be not sold or used for beverage purposes or used for purposes for which tax-free denatured alcohol cannot be lawfully employed. For example, the use of tax-free denatured alcohol is prohibited in any medicinal product for subsequent internal use. If the manufacturer desires to recover completely denatured alcohol incident to any purification process he is required to give a bond to the Collector of Internal Revenue of his district and also register any recovery still employed in the process.

The blended motor fuel of the future will undoubtedly be worked out through the medium of a completely denatured alcohol formula.

Specially Denatured Alcohol

There are seventy authorized formulas for specially denatured alcohol. A number of the more recent ones are applicable to the perfumery industry and certain parts of the pharmaceutical manufacturing industry. It is with the more properly called technical formulas that this article deals.

Application and Bond. To obtain one or more of these special formulas the manufacturer must make an application to the Collector of Internal Revenue of his district, the same officer to whom he pays his income tax. This application states the formulas desired, the products or processes in which they are to be employed and the total quantity in wine, or measured, gallons which will be used in a period of 30 days. If the process involves recovery and re-use of the denatured alcohol, a brief description of the apparatus to be employed must accompany the application. A sample of the product manufactured is required in certain instances and the general formula, if it be a mixture, is frequently necessary. This requirement is in effect in order that the Internal Revenue Bureau may be in a position to determine whether the product or process is one in which tax-free denatured alcohol may be used. The regulations also provide that certain formulas may only be used in a restricted manner and the information set forth in the application is necessary in order to determine these points.

The application must be accompanied by a bond, either a personal bond or a surety bond. The minimum bond that may be filed is $500, which will provide for a purchase and use of not to exceed 99 gal. in a 30-day

Published by permission of the Commissioner of Internal Revue.

period. Increased quantities of alcohol require increased bonds in the same proportion, but the maximum bond that may be filed is $100,000, under which a manufacturer may use practically an unlimited quantity of specially denatured alcohol, subject to the limitations for its use laid down in the application.

The regulations also provide for a locked storeroom in which the specially denatured alcohol is to be kept before use. This provision is only such as would be complied with by any prudent manufacturer in the storing of articles of value.

The Collector of Internal Revenue transmits these papers to the Treasury Department in Washington, where they are acted upon. If approval can be given, under the law and regulations, to the application, the Collector of Internal Revenue is instructed to issue to the manufacturer a permit to use specially denatured alcohol and a withdrawal permit to procure the required quantity in a period of 30 days from any one or more denaturers or bonded dealers in specially denatured alcohol that the manufacturer may designate.

This permit and bond remain in effect until withdrawn or canceled, for cause, and need not be renewed annually. The manufacturer is required to render to the Collector of Internal Revenue a report at the end of each month which will show the amount of denatured alcohol on hand the first of the month, the amount purchased and received during the month, the amount used in manufacturing and the amount remaining on hand at the end of the month. All of these requirements have been made as simple as possible and still enable the department to have knowledge of the movement of tax-free alcohol.

Principal Formulas and Their Uses

An outline of the principal formulas available, and showing a few of their main uses, will be given merely to indicate the scope of the present authorizations.

First, we have the general solvent formulas. They are:

No. 1 — 100 gal. of ethyl alcohol
5 gal. wood alcohol

No. 3A — 100 gal. of ethyl alcohol
5 gal. pure methyl alcohol

(No. 3A differs from No. 1 only in the degree of purity of the methyl alcohol)

No. 10 — 100 gal. ethyl alcohol
2 gal. methyl alcohol
2 gal. benzene

No. 12A — 100 gal. ethyl alcohol
5 gal. benzene

No. 44 — 100 gal. ethyl alcohol
10 gal. normal butyl alcohol

These formulas are widely used in shellacs, varnishes and extraction processes. They have been authorized for over a thousand specific products and it will be necessary to refer to Internal Revenue Regulations No. 61 for the details showing their wide application.

Formula 2B (100 gal. ethyl alcohol and ½ gal. benzene) is widely used as a solvent for nitrocellulose products embracing the manufacture of smokeless powder, artificial silk, artificial ivory and pyroxylin plastics. This formula is restricted as to the uses which will be permitted and this is one of the cases where the manufacturer is required to submit some additional detail as to his process and apparatus.

Formula 13A (100 gal. ethyl alcohol and 10 gal. ether) is used in the manufacture of ether. It also has considerable application as a purifying and recrystallizing medium for certain organic compounds and dyes.

Formula 4 (100 gal. of ethyl alcohol and 1 gal. of a 40 per cent nicotine solution with added coloring matter) is widely used in tobacco products, such as the manufacture of cigars, smoking tobacco, etc.

Formulas No. 5 — 100 gal. ethyl alcohol
65 lb. sulphuric ether
3 lb. cadmium iodide
3 lb. ammonium iodide

No. 11 — 100 gal. ethyl alcohol
100 lb. sulphuric ether
10 lb. cadmium iodide

and No. 19 — 100 gal. ethyl alcohol
100 gal. ethyl ether

are principally used in the photo-engraving industry as carriers or vehicles for sensitized collodion.

Formula No. 18 — 100 gal. ethyl alcohol
100 gal. vinegar containing not less than 9 per cent acetic acid

No. 21 — 100 gal. ethyl alcohol
100 gal. of a solution containing not less than 4½ per cent acetic acid

are used for the manufacture of vinegar, acetates and acetaldehyde.

Formula 20 (100 gal. ethyl alcohol and 5 gal. crude chloroform of a specific gravity not less than 1,400 at 25 deg. C.) is used in the manufacture of chloroform.

Formula 30 (100 gal. ethyl alcohol and 10 gal. of pure methyl alcohol) is used for analytical laboratory purposes.

There are many formulas available for toilet articles and external pharmaceutical preparations, but the reader will have to be referred again to Internal Revenue Regulations No. 61 for the details, as they are too extensive for this article. These formulas are available for the manufacture of lotions and liniments, tincture of iodine, tooth pastes, dentifrices, toilet waters and perfumes. They are of interest chiefly to the pharmaceutical and perfumery industries.

It is not possible to cover the many thousands of authorized uses of denatured alcohol, but a manufacturer who is unable to obtain the information necessary from the Regulations is urged to communicate with the department. New processes are being continually developed that make it desirable for other formulas to be authorized. Data are continually being assembled showing the need of the modification of some of the present formulas.

The Treasury Department is very much interested in obtaining all the information and suggestions possible that will enable it to administer these provisions of the national prohibition act with the greatest possible benefit to industry.

What Is a Chemical Engineer?

At a meeting of the Provisional Committee for the formation of a British Institution of Chemical Engineers the following definition was agreed upon: "The chemical engineer is a professional man experienced in the design, construction and operation of plant in which materials undergo chemical or physical change."

Fundamental Physical and Chemical Properties of Commercial Lime I—The Available Lime Content

The First of a Series of Articles Describing the Experimental Work in the Laboratories of the National Lime Association—Variations in Available Lime Content and Their Significance

By M. L. Holmes and G. J. Fink
Chemical Department, National Lime Association

THE extensive ramification of the uses of lime[1] in our industrial life and the enormous increase during recent years in the use of lime[2] by the chemical industries and in technical processes have served to show the lack and to emphasize the urgent need of comprehensive information about the fundamental physical and chemical properties of this material. Before the most intelligent use can be made of such a chemical as lime we must first know its properties and how it will function.

The National Lime Association undertakes to serve the user of lime in every possible way and in accordance with that policy has under way an extensive investigation in which limes from every section of the country are being studied for the purpose of obtaining, upon one set of samples, comparative data on all of the important characteristics of this material. This work should have an important bearing upon every industrial use of lime.

Although there may be abundant data concerning the chemically pure oxides and hydroxides of calcium and magnesium, there are very little published data on the commercial limes as now found on the market. By the term commercial lime, we refer to the three and one-half million tons of product made yearly in this country by calcining limestone and which is placed on the market without any further processes of chemical purification. That this material may be quite different from corresponding c.p. chemicals is evident from the following definitions as adopted by the American Society for Testing Materials:[3]

"Quicklime is a calcined material, the major part of which is calcium oxide or calcium oxide in natural association with a lesser amount of magnesium oxide capable of slaking with water.

"Hydrated lime is a dry powder made by treating quicklime with enough water to satisfy its chemical affinity under the condition of its hydration. It consists essentially of calcium hydroxide or a mixture of calcium hydroxide and magnesium oxide and magnesium hydroxide."

Commercial limes are further classified by the A.S.T.M. on the basis of the alkaline-earth oxide ratio as calcium and magnesium limes. In common practice calcium lime is one containing 85 per cent or more total CaO and magnesium lime is one containing more than 30 per cent MgO. In case the CaO content is very high, it may be called high-calcium lime and in case the magnesium oxide is considerably more than 10 per cent it may be called high-magnesium lime.

Method of Manufacture

Most of the quicklime produced in this country is made in shaft kilns in which the selected limestone is subjected to the temperature of the decomposition of calcium carbonate for a time sufficient to drive off all the carbon dioxide. Details of the precautions observed in producing a high-grade material of uniform quality may be found in previous publications.[4]

Hydrated lime is now made by mechanical processes which vary somewhat, but all involve the thorough mixing of the quicklime with the predetermined quantity of water required for complete hydration and the maintenance of the most favorable conditions for such hydration. The actual process of hydration is followed by storage and mechanical purification such as air separation or screening. Further details are given in the above-mentioned references.

Samples Used in These Investigations and Handling

The samples of lime used in these investigations were obtained from lime plants located in practically all sections of the country and representing all types of lime varying widely in physical properties and ranging in chemical composition from the high-calcium to the high-magnesium type. The samples represent the average quality furnished continuously to the trade by these companies.

The samples were received and stored in airtight tin cans, each being assigned a key number.

The quicklimes were crushed to pass a quarter-mesh sieve and samples for all determinations were obtained by quartering in the usual manner as specified by the

A.S.T.M. The hydrated limes were quartered directly to obtain a sample of proper size for each determination.

The hydrated lime samples were not made from the particular samples of quicklime used in these tests, but the hydrated lime and quicklime designated by the same key number were obtained from the same plant and are products of the same quarry.

The condition of these samples as tested is indicated by the low loss on ignition as given in Table I of this paper, showing that the samples were in good condition when tested.

The results of these investigations will be reported in a series of articles, of which this, on the available lime content, is the first. The series will include papers on specific gravity, per cent pore space, rate of settling, volume in water, fineness, slaking characteristics, volume, weight and water content of putty, plasticity, sand-carrying capacity, colloidal properties, optical properties, chemical reactivity toward solutions, solids and gases, chemical composition, etc. The interrelationship of these various properties will be pointed out as they are taken up and a final article will summarize all of the data.

I. The Available Lime Content

During recent years it has become more and more the practice to base specifications for lime for certain uses upon the available lime content, although there seems to have been very little information bearing directly upon this property of commercial lime. This investigation was undertaken to supply this much-needed information, having in mind particularly the relative amounts of available lime in quicklime and hydrated lime on the one hand and calcium and magnesium limes on the other hand.

By the term available lime is meant that portion of the total oxide content of the lime, either quicklime or hydrated lime, calculated as CaO, which is easily soluble in water and is thus available as a source of hydroxyl ions. All figures for available lime are expressed in terms of percentage of the non-volatile portion.

After considering the various methods which have been proposed for determining available lime, it was decided to use the Bureau of Standards modification of the Scaife method,[6] recently adopted by the American Society for Testing Materials, which is quoted as follows:

"Place 1.4 grams of the carefully prepared and finely ground (passing 100 mesh) lime in a 400-c.c. beaker, and 200 c.c. of hot water, cover, heat carefully and then boil for 3 minutes.

TABLE IV—MAGNESIUM LIMES

N.L.A. Lime No.	Available Lime: Quicklime	Available Lime: Hydrate	Difference	Per Cent Difference
23	54.91	52.91	2.00	3.64
52	55.18	44.15	11.03	19.98
65	48.98	48.59	0.39	0.80
71	53.73	51.01	2.72	5.62
74	51.77	49.55	2.22	4.28
75	59.45	58.35	1.10	1.85
103	55.35	48.25	7.10	12.79
Average	54.19	50.40	3.79	6.99

"Cool, wash down cover, add two drops of phenolpthalein and titrate with *N* hydrochloric acid, adding the acid dropwise as rapidly as possible and stirring vigorously to avoid local excess of acid. When the pink color disappears in streaks, retard the rate of addition of acid somewhat, but continue until the pink color disappears entirely and does not reappear for 1 or 2 seconds. Note the reading and ignore the return of color.

"Repeat the experiment, substituting for the 400-c.c. beaker a 1-liter graduated flask carrying a one-hole stopper fitted with a short glass tube drawn out to a point. Cool and add dropwise and with vigorous stirring 5 c.c. less acid than before. Call the number of c.c. used *A*. Grind up any small lumps with a glass rod flattened at one end, dilute to the mark with freshly boiled distilled water, close the flask with a solid stopper, mix thorougly for 4 or 5 minutes and let settle for half an hour.

"Pipette a 200-c.c. portion, add phenolphthalein, and titrate slowly with 0.5 *N* hydrochloric acid until the solution remains colorless on standing 1 minute. Call this additional number of c.c. *B*. Then the percentage of available CaO equals $2A + 5B$."

The available lime data tabulated in Tables II, III

[6] *Chem. & Met. Eng.*, vol. 25, p. 740 (1921).

and IV are recalculated to the non-volatile basis, by application of the following formula:

$$\text{Percentage available lime on non-volatile basis} = \frac{\text{Percentage available lime in samples as used}}{100 - \text{loss on ignition}}$$

The figures therefore represent the percentage of the non-volatile portion of the sample, which is water-soluble under the conditions as described.

In Table I are given the data obtained on commercial quicklimes and in Table II the corresponding data for hydrated limes. In Table III is given the available lime content of typical calcium quicklimes in their corresponding hydrates, and in Table IV similar data are given for typical magnesium limes.

Discussion and Conclusions

The data in Table I show that there is a large variation in the available lime content of commercial quicklimes and that in a few special instances it is possible to obtain at the plant where made a lime running as high in available lime as 96 per cent of the non-volatile portion.

The data in Table II show a variation for hydrated limes similar to that in Table I with certain hydrates running somewhat higher than 90 per cent.

It is evident from the data in Tables III and IV that calcium limes have a much higher available lime content than magnesium limes and on the other hand that the reduction in available lime content by the hydration of magnesium limes is less than that of calcium limes.

It is also evident from the averages in Tables III and IV that the tendency for the quicklimes, both calcium and magnesium, is to have a higher available lime content than the corresponding hydrates as determined by the A.S.T.M. method. This difference is not large and is insufficient to outweigh the obvious advantages of hydrate for certain purposes. It is, however, consistent enough to warrant the conclusion that certain conditions obtain in modern mechanical processes of hydration which tend to reduce the available lime content. The data for several of the samples, on the other hand, show that it is possible to hydrate so as greatly to minimize this tendency.

There are several causes which may possibly contribute to a reduction in the available lime content during the process of mechanical hydration and mechanical treatment. These causes may be chemical or they may be physical. It has been suggested that it may be a case of molecular aggregation whereby a portion of the lime is rendered physically unavailable, or it may be a case of molecular transformation by local burning during hydration which might change some of the lime into a less soluble form. The state of moisture and local temperatures in the hydrator may also be conducive to certain chemical reactions between the constituents in the lime which would produce a small percentage of an insoluble product. Further work to be reported later will add more information on this subject.

Protection of Aluminum

Much work has been done in recent months by the corrosion committee of the British Institute of Metals on the preparation and testing of protective coatings of molybdenum compounds and aluminum hydroxide for use in aluminum and light alloys. This work is still in progress, and will eventually be published.

Etching to Develop Overstrain

An etching process originated by A. Fry, of Krupp's research laboratory, Essen, Germany, develops new markings in overstrained steel bearing close relations to lines of maximum shear as determined mathematically.[1] Fig. 1 gives the appearance at natural size of a piece of boiler plate, bent flat upon itself cold.

Specimens are prepared for microscopic or macroscopic examination in the usual manner, care being taken particularly to avoid any distortion of the specimen during grinding and polishing. Before examination they must be "suitably" reheated, ½ hour at 200 deg. C. being suggested.

For microscopic investigation the etching medium is prepared as follows: Concentrated HCl 400 c.c., H_2O 30 c.c., ethyl alcohol 25 c.c., cupric chloride crystals 5 grams. The carefully polished specimen is etched briefly and if necessary repolished and re-etched until the desired results are obtained. The etching medium

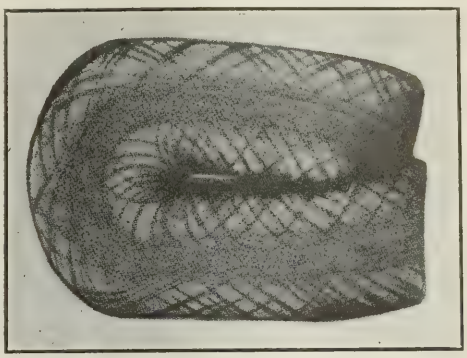

FIG. 1—PIECE OF BOILER PLATE, BENT FLAT UPON ITSELF COLD

for macroscopic investigations consists of concentrated HCl 120 c.c., H_2O 100 c.c., cupric chloride crystals, 90 g.

The specimen is immersed in this solution for from 1 to 3 minutes, then removed and rubbed with finely pulverized cupric chloride on a rag moistened with the etching medium until the desired contrast is maintained. The specimen is then dried without rinsing, washed with ethyl alcohol and then thoroughly dried.

Both solutions are too strongly acid to deposit copper upon the iron. The etched pattern should consist of dark and light bands, the dark color being ascribed by Fry to the formation of iron hydride. These bands correspond to the location of maximum shearing stresses in the material and by their presence indicate how much of the material has received cold-work—that is, has been plastically deformed.

List of Petroleum Laboratories Being Compiled

A list of commercial laboratories specializing in the analysis of petroleum products is being compiled by the United States Bureau of Mines. Laboratories are being asked to indicate the particular tests outlined in Technical Paper 298, "Methods of Testing Petroleum Products," which they are prepared to perform. Inquiry is being made especially as to whether laboratories are equipped (1) to make analyses of natural gas, especially the determination of gasoline content, (2) to examine crude oils, oil shales and oil sands, and (3) to undertake petroleum problems of a research nature.

Pouring Sound Ingots of Fine Steel*

Americans Teem Cool Steel in Bottom-Cast Ingots—Surface Cracks Controlled by Shape and Condition of Mold—Pipe Reduced by Retaining Hot Metal in Ingot Top and Slow Cooling—Ingot Should Be Stripped Fairly Early and Buried in Ashes

ON PAGE 929 of *Chemical & Metallurgical Engineering* for May 17, 1922, was presented an article on "Fine Steels From the Acid Open Hearth," wherein was explained in detail the method of making fine nickel steel and getting it into the ladle at the proper temperature. The present article is a continuation of the subject matter, and deals with the proper procedure to convert the liquid steel into sound ingots.

American practice is to pour large ingots of nickel steel with fairly cool metal, avoiding surface cracks at the risk of retaining inclusions in the metal. Europeans purposely pour very hot, holding that the advantages accruing to the method counteract the surface cracks which form; cracks which can be chipped out and which are regarded by the workmen as signs of a quality ingot.

Surface Cracks

Hot metal entering a cold mold is chilled and a crust rapidly solidifies, thicker at the bottom. As this crust cools it contracts; as the mold heats it in turn expands; the solidifying ingot therefore loosens in the mold and loses its outside support. If the steel is poured so rapidly or so hot that the crust grows more slowly than necessary to resist the interior pressure of liquid metal, it will burst. To avoid this, American metallurgists pour "cold" and slow. Surface cracks are also affected by the condition and shape of the molds, as will be shown later.

However, if pouring is too slow, the top edges of the steel may crust over, and this crust may be folded back against the mold as the level rises; it either remains unmelted or is remelted; if the former, it forms a scab which must be cut out; if melted, it puts oxidized iron into the ingot. Spittings and splashings from the ladle stream striking and sticking to the mold are sources of similar defects in top-poured ingots.

Cold pouring, on the other hand, certainly retains in the ingot any inclusions which the steel possessed on being tapped from the furnace or picked up subsequently from its containers. Large ingots which will not surface crack must be poured in the mushy stage (where the metal consists of low-carbon austenite crystals growing from a higher carbon mother liquor), a state which does not permit many lighter solids to rise to the surface. An obvious corrective is to make clean steel and handle in clean containers.

Hot-poured metal solidifies slowly and causes columnar crystallization in the outer layers of steel, a condition known as "scorched," and to Europeans not especially disliked, except that such an ingot is quite tender under forging.

If a prism of metal could be cooled so that the temperature was the same, surface to axis, it would solidify into a denser mass, without internal cavities. But ingots freeze from the outside in, and from the bottom up. Consequently the interior may be still molten when the shell is relatively cold and fairly rigid. As the whole mass continues to cool, the outer zones also cool and contract, but their contraction is not as great as demanded by the contraction to be endured by the hotter inner zones. What results is a mass of compressed metal toward the surface, gradually changing through a zone practically unstrained into a mass of interior metal strained in tension. If at any time—even long after the entire mass has solidified—the inner material is stretched beyond its resisting ability, a cavity opens up, immediately closed by (in fact anticipated by) hotter metal sagging into place if the temperature is high enough to allow viscous or plastic flow under the force of gravity. Otherwise a permanent cavity or pipe remains. Evidently it is necessary to feed the interior portions of the ingot with hotter metal to the very last if the pipe is to be restrained. Other things being equal, this is better done in big ingots than in small.

Hot Tops

Various well-known devices are used to keep the top of a solidifying ingot hot. Among these are "hot-tops" to the molds; sinkheads; placing the large end of the ingots uppermost; pouring slowly at a low temperature and at the top of the ingot (especially at the last); and making the mold walls thicker below than above so that they may cool the bottom of the ingot faster than the top. Fig. 1 gives details of this practice. Lagging the upper part of the mold with insulating material also helps retain the necessary heat at this region.

Sink-heads of sand are likely to be the source of many inclusions if the ingot is top cast. Tops kept hot by coke or charcoal fires will be carburized and this extra carbon is likely to be carried down to considerable depths by diffusion or feeding.

Eventually from 20 to 30 per cent of the steel will be discarded from the top, as being fundamentally unsound from pipe, or containing segregated impurities (sulphur and phosphorus). The lower figure is sufficient for well-made thoroughly deoxidized clean steels properly cast with hot tops.

Since steel cools more rapidly in the mold than in the ladle, slow top pouring *shortens* the pipe by furnishing liquid metal to the top long after the metal in the base has chilled. For the same reason, cold pouring *raises* the pipe. Suppose the extreme case where metal would solidify almost immediately on entering the mold. This approximates the condition of uniform cooling, and tendency to pipe is eliminated because there is small difference in temperature, sides to axis, and consequently small difference in the internal stresses.

Molds should taper just enough so that the ingots can be stripped easily when the faces are at about 85

*A digest of a paper entitled "Acid Open-Hearth Process for Manufacture of Gun Steels and Fine Steels," presented by W. P. Barba and Henry M. Howe before the February meeting of the American Institute of Mining and Metallurgical Engineers.

eg. C. (1,560 deg. F.) and the corners black. Any xcess taper causes difficulties when attempting to reeat an ingot uniformly, and usually involves extra ork in forging. Simultaneous contraction of the cooling ingot and expansion of the heating mold might be xpected to leave a gap between the two, even with no aper. But much of the contraction is counteracted by he internal ferrostatic pressure. Furthermore, the old is not truly smooth, even though it is carefully repared, coated with a graphite wash and polished. Diminishing the diameter $\frac{1}{16}$ in. to the running foot is ood practice, for both large and small ingots. The xtra contraction in a large ingot (resulting from its igher average temperature when the outer layer is omewhat rigid) would lead one to expect that it could e poured in a mold with a somewhat slighter taper. ut this extra contraction seems to be restrained by xtra internal resistance.

If a round gutter pipe is filled with water and frozen t will burst. If a fluted gutter pipe is treated similarly. he curved sides buckle a little and do not burst. For imilar reasons, ingots are fluted to prevent longitudinal urface cracks.

Transverse cracks are often caused by the top of the ngot being hung from the mold by a fin or by some oughness before the sides are cold and strong enough o bear the weight of the metal below. Conditions are ggravated, of course, if the metal is seized and held ast at both ends. Slightly protruding corners on the ngot are of advantage in counteracting these cracks, ince they cool more rapidly and quickly form solid pilars to support the weaker portions.

A fluted octagon seems to be the best cross-section. t possesses eight protruding corners, protruding nough to cool somewhat quicker than the faces, and yet ot enough to fold over when being forged or to be urned during reheating. To avoid this last contingency a square ingot must have rounded corners, but ven so, there is a pronounced tendency to develop diagonal planes of weakness corresponding to the junction of columnar crystals growing in from adjacent sides, a tendency which is counteracted in part by thinning the mold, as shown in Fig. 2. Square ingots designed for rolling are shaped in this fashion to facilitate blooming and manipulation; forging ingots are frequently made with convex sides.

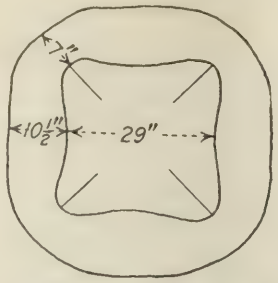

FIG. 2—ROUNDING AND THINNING THE EDGE OF A SQUARE MOLD

The ratio of length to thickness for ingots of tender alloy and high-carbon steels is approximately as follows:

Size	Length ÷ Diameter	Size	Length ÷ Diameter
4 in.	Up to 9	40 in.	Not more than 2½
18 in.	3.5 to 5	60 in.	Not more than 1¾

If the 40- and 60-in. ingots are intended for shafts, the length may be increased somewhat beyond these ratios, because inclusions are not so harmful in shafting as in guns.

Top Versus Bottom Pouring

Though bottom pouring requires more apparatus, more equipment and more time for setting up than is usual for top pouring, it has the greatest outstanding advantage that each individual ingot can be watched during its making, and the speed of the incoming stream of metal adjusted in exact conformity with the requirements of the temperature and composition of the metal and the size and shape of the mold. These and all the other factors governing the production of a successful ingot are found to be under much more thorough observation and control in bottom pouring than has as yet been possible in top pouring, except when pouring from a lip or teeming through a head box.

The disadvantages attending bottom pouring, noted above, together with the prohibitive proportion of scrap metal from runners, cause small crucible-steel ingots to be top poured; larger ingots of fine steel from 9 to 55 in. in diameter and weighing up to 150,000 lb. are bottom poured, often in groups from a central gate, thus giving great uniformity among small ingots of a given lot. Still larger ingots, especially when very high and requiring more than one ladle of metal, are half or one-third bottom poured, and the upper part teemed from above. In the latter case, the pool already formed prevents splashing and scouring against the bottom of the mold, a great drawback to top pouring any but the shortest ingots. Furthermore, the surface of large or wide ingots may be observed even when top pouring, and its indications are not so much disturbed by the impact

FIG. 1—DIMENSIONS OF MOLDS THICKENED AT BASE AND THINNED AT TOP

of the metal. Lastly, the top of a slender ingot of any weight or of a mold having brick-lined sink-heads should be filled from above, because this puts hot metal directly where it is needed (to reduce pipe) with the minimum disturbance to the cooler underlying metal. In fact the churning of the axial regions of a bottom-poured ingot hemmed in by the already solidified walls leaves behind an inverted cone of mushy metal up the axis of an ingot of practically uniform temperature. An entire lack of temperature gradient bottom to top would produce a deep pipe because the fissured lower metal is not overlain by hotter, more plastic metal which can sag into the cavity. Fortunately temperature uniformity does not persist long after pouring has ceased in large ingots, on account of the much slower solidification of the upper part of the inverted cone of fluid metal.

If the requisite degree of care is given to the selection of the brickmaker, the material from which the bricks are made, the nature and the burning of the bricks, and the care with which they are fitted together into gates and runners and the joints protected, it will be found that there is only a negligible amount of inclusions due to fluxing of the inner surface of the bricks by the stream of metal entering the molds.

Very high molds are sometimes spoiled by "run outs." In every case great care must be taken to insure that the passageways are stout enough not to be burst by the internal pressure. During the top pouring of the last portions of very high ingots, however, the runners used at the start freeze and effectually prevent leakage from the mold.

Precautions During Pouring

Metal near the ladle stopper is chilled and often contains inclusions. Therefore about 400 lb. of steel is first teemed to scrap, the stopper carefully closed, the ladle centered over the regular mold, and teeming started as soon as possible. The top hole, stopper plug and lining of the ladle bottom should be as refractory to the scour of rushing metal as possible, for fluxing of these parts is a fruitful source of non-metallic inclusions in fine steel.

The interval between tapping and teeming and the rapidity of teeming are governed by the melter's judgment as to the temperature at which the steel left the furnace, and by the size and number of ingots into which the charge in the ladle is to be poured. The length of time occupied in teeming each ingot should be recorded carefully for the melter's guidance in future cases. If today's ingots show external cracks and are tender to forge, he will infer that he should pour a little cooler. If on the other hand, laps, scabs and cold shuts show, especially at the corners, the ingot was poured a little too cool. Another source of information is the condition of the ladle after pouring. A slight skull should remain after cold pouring, representing material too pasty—too near the solidus—to flow to the nozzle. Rate of pouring and temperatures are therefore regulated by the melter's judgment, skill and experience with former ingots and heats.

The above indications are derived from conditions existing after the job is done, and any trouble can be corrected only in future casts. The most important evidence *during* the casting is the appearance of the top of the metal in the mold. It is a common saying that the appearance of bottom-poured steel as it rises in the mold should be that of "breaking cream." This is readily understood when we remember that the meta poured at the proper temperature is an emulsion muc like that of the suspended butter fat of thick crean Both are subject to crusting over with a very thi crust. In steel, this crust, caused by the cooling effec of the air in the neighborhood of the mold, is quickl remelted by the hot steel rising from below if the pour ing temperature is proper.

If cold pouring is stopped, even for a very short time a defect known as a "stop pour" forms where the uppe surface slightly freezes, oxidizes and is not remelted This defect extends into the metal an unknown depth Stop pours are fit cause for rejection in gun steels and in other fine steels the ingot should be sheared a the defect. Slight stop pours may not be detectable i the ingot, and are often glossed over in rolling, showing up only when machining starts. Forging is more likely to make them evident.

Stripping, Cooling and Reheating

As soon as the solid walls have grown thick an strong enough to support the interior fluid safely, th molds are stripped. Removal of this "chill" causes th surface to cool at a slower rate, the temperature gra dient, surface to axis, becomes less and the pipe-forming tendency is therefore reduced. Liability to interna and external cracks is also decreased. Further retarda tion in cooling may be had by burial in ashes or bitu minous coal; still slower cooling in soaking pits passes to another danger—viz., growth of very large primary crystals. Top-poured ingots may advantageously be stripped somewhat earlier than bottom-poured, and permitted to cool in the air until the solidification of the wall has progressed to such a point that the outer surfaces are under a fairly high stress. They should then be buried. Such practice safely expedites the cooling.

Reheating of ingots and blooms of fine steel should be done extremely slowly, so that differential expansion caused by one zone or region being hotter than its neighbors may not strain the metal beyond its strength and cause internal cracks.

Summary

After the metal has been properly made and thoroughly degasified, it is poured relatively cold in order to restrain segregation, columnar and coarse crystallization. Piping is reduced by inverted ingots, and by rapid pouring at the end.

External cracking, occurring when the surface regions are just solidifying, or later when passing through the "blue heat" (especially in coarse-grained steel), may be guarded against (*a*) by tapering the mold so the ingot will free itself and not hang and (*b*) by fluting the mold.

"Internal cracks including flakes must be restrained:

(*a*) "By interrupting the relatively rapid cooling in the mold and replacing it with slower cooling in ashes as soon as the ingot has solidified sufficiently to be moved without danger of cracking.

(*b*) "By saddening (giving a succession of light reductions under the hammer or press, or in a rolling mill) and thereby substituting strong cohesion and toughness for its initial fragility due to its having a very coarse crystalline sugar-like structure.

(*c*) "By retarding the heating of the ingot for forging and that of the forgings themselves, so as to lessen the thermal stresses.

(*d*) "By as great freedom from inclusions as possible."

The Technology of the Carbon-Electrode Industry—VI Cleaning, Testing, Machining and Shipping

In Concluding This Series of Articles the Author Reviews the Finishing Steps in Electrode Manufacture and Discusses the Properties and Other Factors Affecting Requirements for Use in Electrolytic and Electrothermic Applications—Economics of the Industry and the Trend of Developments

By Charles L. Mantell
Division of Industrial Chemical Engineering, Pratt Institute, Brooklyn, N. Y.

IN THE articles which have preceded this one the discussion of carbon-electrode manufacture has been carried through the baking process.* The green electrodes, which are made of a combination of carbonaceous materials, the properties and qualities of which vary widely with temperature changes and which have a high electrical resistance and a low tensile strength, have now been changed into baked electrodes, consisting of material with uniform properties over a wide temperature range and with lower electrical resistance and higher tensile strength than the green electrode.

The electrodes as they come from the baking furnaces are dirty—that is, they have adhering to their surfaces some of the packing material in which they were baked. In the case of carbons with which a correctly graded packing material was used, most of the packing dust can be easily removed by knocking or brushing. Sometimes, however, cases of carelessness occur when use has been made of a low fusing packing dust, high in ash content. As a result, large lumps of packing material are attached to the surfaces of the carbons and are removed only with difficulty. At other times sufficient care may not have been taken in placing packing between all of the surfaces of the carbons when loading the furnace. The result is that when the carbons are softened in the early stages of baking, they become welded together and when baked in this manner give malformed electrodes. These, of course, go to the scrap pile.

The Methods of Cleaning

Methods of cleaning differ according to the shape of the finished electrode. They may be divided into three general methods—(1) brushing, (2) stoning and (3) tumbling. Although the method used depends primarily upon the shape or form of the finished electrode the amount of packing material to be removed must be adjudged a factor of secondary importance. Plates, of course, could not be tumbled in a tumbling barrel without an excessive breakage loss. The same holds true for long, small-diameter electrodes. Electrodes with square or rectangular cross-section cannot be tumbled, as their edges would be rounded off as a result of the process.

Usually two or all three methods are employed in conjunction with one another. Carbons as they come from the furnace are sent to some sort of power-driven brush with steel wire bristles. Plates can be cleaned quickly with a pair of brushes somewhat wider than the width of the largest plate, mounted horizontally and rotating in opposite directions. The plates are cleaned by passing them between the brushes. Square and rectangular shapes are often brushed on a similar type of machine, but in which the brushes are mounted vertically and the carbon passed through twice, or through two successive machines, being given a quarter turn in the plane of its cross-section between the first and second brushings so that all sides may be cleaned. Round electrodes are often cleaned on the periphery of horizontal or vertical wheels, and in some cases by steel brushes mounted on the inside of revolving rings.

Carbons which cannot be completely cleaned on the brushes are finished on the stoning wheels. These are large wide-faced wheels of emery or other similar abrasive material. Small round electrodes whose length does not exceed more than six times their diameter can be very successfully and readily cleaned by tumbling in steel tumbling barrels loaded about seven-eighths full. Cast-iron, star-shaped jacks (about $\frac{3}{4}$ to 1 in. size) are used to assist in the cleansing operation. The tumblers are horizontal steel cylinders with removable covers, for loading and unloading, mounted on hollow shafts connected to each end. One end is open to the air through the hollow shaft, and the other is connected to piping leading to the exhauster of a dust-collecting system which discharges into some sort of collector, often of the cyclone type. Electrodes which have not been sufficiently cleaned by tumbling go to the brushes and stones for final cleaning.

Cleaning practice in the various electrode plants differs materially even when the same type and size of product are being handled. In the case of small electrodes it was formerly the practice to brush all electrodes, and tumbling barrels were used to clean only those which were too dirty for the brushes. In some modern plants, as a result of scientific management, this procedure has now been completely reversed and considerable saving effected. All electrodes are tumbled for a short while and only those still unclean after this procedure are brushed and stoned. Records of this method with small round electrodes show that all but a small percentage are cleaned without brushing.

It is general practice to equip all cleaning apparatus with suction hoods, connected to a dust collector. This is done with the view of supplying better working conditions, and also to recover as much as possible of the packing material removed from the carbons.

Mention has been made in a previous article[23] of the

*For Parts I to V, see *Chem. & Met. Eng.*, vol. 27, Nos. 3, 4, 5, 6 and 7, pp. 109, 161, 205, 258 and 312.

[23]See Part V, *Chem. & Met. Eng.*, vol. 27, No. 7, p. 312, Aug. 16, 1922.

resistivity of the carbon electrode. Its discussion, however, has been delayed to this point, since its determination is usually made in the plant testing laboratory, which is generally located in or near the cleaning and shipping departments. In general two methods of testing are used:

1. Measurement is made of the voltage drop, with a given current, through a known distance of an electrode having a uniform cross-section. Direct current is passed through the whole electrode. Resistivity or specific electrical resistance is then obtained by the use of Ohm's law and the formula for specific, calculated from total resistance. The formula[24] $\rho = SE \div lI$ gives a result in ohms per inch cube when S and l are expressed in square and linear inches respectively, or per centimeter cube when S and l are expressed in square and linear centimeters.

For ordinary purposes it is sufficient to measure resistance to 0.0001 ohm, a precision of about 5 per cent. By this method the voltmeter will show a voltage drop due to resistance through the whole potential circuit—that is, it will include voltage drop due to resistance of the potential contacts and the lead wires. The resistance of the potential contacts may be practically eliminated by drilling small mercury cups in the carbon or pressing the contact pins against the carbon at a pressure of about 3,000 lb. to the square inch when using a millivoltmeter having a resistance of 1.07 ohms.

2. Measurement is made directly of the resistance of an electrode or a portion of an electrode by comparing it with a standardized resistance by means of a resistance bridge. This method is more accurate than the first, because it is a zero method and comparison is made directly with a standardized resistance the accuracy of which can be made very high. The instrument generally used is the Leeds & Northrup Kelvin double bridge ohmmeter.

Resistivity is calculated from the formula $\rho = (S \div l)R$, where ρ = resistivity, l = length, S = cross-section, R = scale reading of resistance.

Where measurement is made of the circumference in the case of round electrodes, this formula becomes $\rho = \text{cir } R \div 12.57\,l$.

[24] ρ = specific resistance, S = cross-section, E = voltage drop, I = current in amperes and l = length or distance.

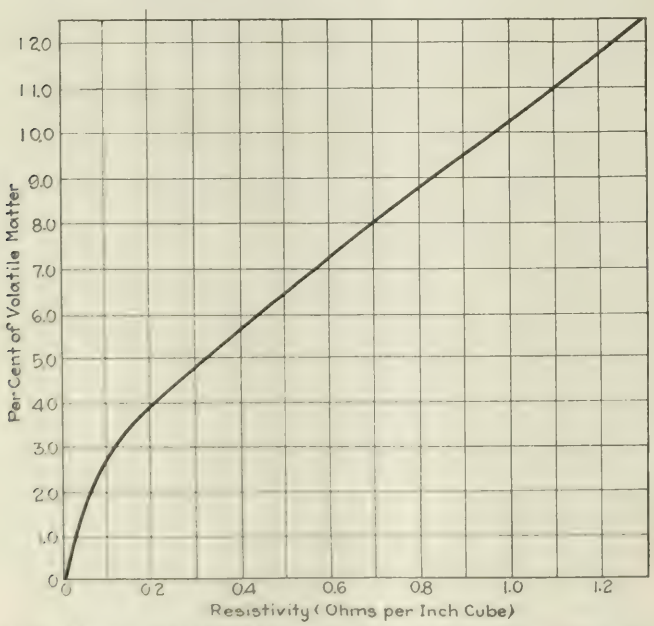

FIG. 36—RESISTIVITY-VOLATILE MATTER RELATION OF CARBON ELECTRODES

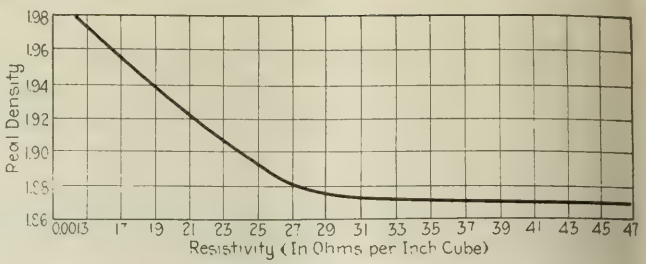

FIG. 37—RESISTIVITY-REAL DENSITY CURVE FOR CARBON ELECTRODES

In plants where large numbers of the same sized electrodes are being made and tested, it is usual practice to provide permanent potential and current contacts. Potential contacts are often V-shaped, made of copper, brass or steel, with knife edges on the inside of the V. While making the measurement, the electrode is supported in a horizontal position by the knife edges. The pressure of the weight of the electrode against the knife edges of the V is sufficient to afford good contact. Current contacts are often copper, brass or steel plates in which there are imbedded short cylindrical rods, pointed at the ends. The points of the rods are pressed against and into the ends of the electrode by pressure exerted against the plates in which the rods are imbedded.

Factors Affecting Resistivity

The electrical resistivity of carbon electrodes varies inversely as the elemental carbon content, directly with the ash content, directly with the percentage of volatile matter and inversely as the apparent and real densities. As the percentage of elemental carbon increases, the percentage of ash and volatile matter will decrease and the resistivity will decrease. As the percentage of ash increases, there will be more and more of materials whose known resistances are greater than that of carbon, and the resistivity of the material as a whole will increase.

The curve in Fig. 36 shows the resistivity-volatile matter relation of carbon electrodes. The relation between real density of electrodes to resistivity is shown in Fig. 37.

Resistivity increases with decreases in apparent density; and as a result, increases with increases of porosity. As the percentage of graphite in electrodes increases, the resistivity will decrease, since graphite has a resistivity of about one-fourth that of amorphous carbon. The real density of an electrode is the density of the material of which it is composed, free from pores or voids. It may be considered as a measure of the chemical composition of the material and increases as the amount of hydrogen in the hydrocarbons in the electrode decreases. It is thus an indication of the relative rate of oxidation of the electrode, it being a general rule that hydrocarbons high in hydrogen are most readily oxidized.

The apparent density—that is, the density of the carbon including the pores or voids—may be considered as a characteristic of the mechanical structure. It is influenced by every process through which the carbon goes in the manufacture of the electrode and is in general a measure of the relative rate of disintegration of the electrode in use. For large electrodes the most

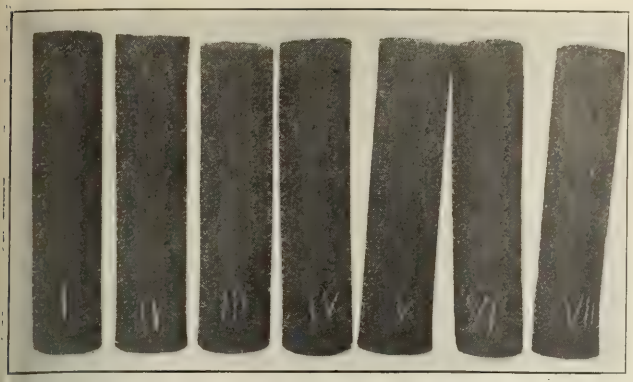

FIG. 38—ROUGH-SKINNED ELECTRODES
(No. 1 is smooth-skinned for comparison)

FIG. 39—OTHER EXAMPLES OF DEFECTIVELY BAKED ELECTRODES

atisfactory method is to weigh the whole electrode and alculate its volume from its dimensions. Where W quals weight and V volume, then

$$\frac{W \text{ (in lb.)}}{V \text{ (in cu.in.)}} = A.D. \text{ (apparent density) in lb. per cu.in.}$$

r more commonly

$$\frac{W \text{ (in grams)}}{V \text{ (in c.c.)}} = A.D. \text{ in grams per c.c.}$$

To obtain a precision of 2 per cent, the weight and ength should be measured to 1 per cent and the diam- ter or periphery to 0.5 per cent.

Physical Inspection

The cleaned carbons are inspected for cracks, flaws, hape, surface roughness and uniform hardness through- ut the length of the electrode. Cross checks, splits nd die rings, discussed previously in reference to the reen carbon,[25] may have been developed during the aking process either as a result of defects which lipped by the green inspection or originated in the aking furnace. Misshapen electrodes go into the scrap ile. Occasionally the furnaces may produce electrodes which are perfect except for an end which is so soft that it can be cut off with a knife or easily knocked off. Such carbons are rejected. Unusually rough-surfaced carbons, resulting from a blistered or rough condition in the green or from adhering packing material which has become a portion of the electrode and cannot be removed, are thrown out. All scrap resulting from the inspection of cleaned electrodes is returned to the manufacturing process by being used as calcined material in the grinding and pulverizing mills. Figs. 38 and 39 show some finished small round electrodes with rough surfaces.

It is at this point, along with physical inspection, that electrodes are rejected for resistivity above the standard and apparent density below the standard. Carbons of high resistivity are termed "re-bakes" and are returned to the furnaces to be again submitted to the baking process. Electrodes very much below the standard for apparent density because of excessive porosity are thrown into the scrap pile, to go back into process as unground calcined material.

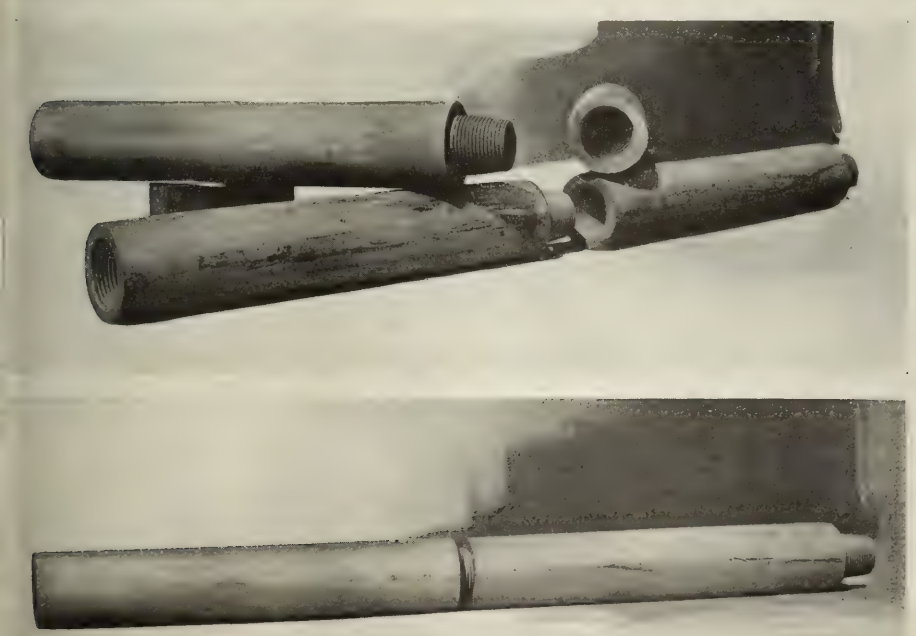
Machining Electrodes

Cleaned carbons, after passing inspection, are sent directly to the shipping room if they are to be used in their present form. If they are to be threaded or tapped, they are sent to the threading or machining departments.

Good amorphous electrodes are comparatively hard and more or less difficult to machine. High-grade machine-steel working tools are required and the threads are cut, holes drilled and tapped in the same manner that a piece of metal might be worked. Amorphous electrodes have a marked abrasive effect on the tools used in machining them—a fact which necessitates frequent regrinding and replacement. It is the opinion of the author, however, that the comparative difficulty of machining amorphous electrodes has been somewhat overstressed and made to seem more difficult than it really is.

Fig. 43 shows the threading and inspection departments of the Niagara Works of the National Carbon Co.

[25] See Part V, *Chem. & Met. Eng.*, vol. 27, No. 7, p. 312.



FIGS. 40 AND 41—GRAPHITE ELECTRODES THREADED FOR CONTINUOUS FEED

There are two methods by which electrodes may be joined. In the first, both ends are drilled and tapped so that a small threaded plug of electrode material may be screwed in the end of one electrode and the adjacent end of the next one. This method of joining electrodes is now largely used[26] for large electrodes. In the case of small electrodes, it is replaced by one in which one end of the electrode is threaded, and the other drilled and tapped so that the end of one electrode can be screwed directly into the end of another. This method will be better understood by referring to the illustrations of graphite electrodes threaded for continuous feed as shown in Figs. 40 and 41. The last illustration shows the method of assembly.

Shipping

After machining, the electrodes are inspected, those at fault returned to be re-machined if the fault can be corrected, or if not, are sent to the scrap pile to be used in the process as unground calcined material. The next step in process is shipping the finished product.

When a through shipment can be made, electrodes in carload lots are carefully packed and braced in the car without being boxed. In less than carload lots, it is usual practice to employ wooden boxes, the sizes of which vary according to the size of the electrodes. Sawdust is used to hold the carbons in place and prevent breakage. The Acheson Graphite Co. uses a case having a gross weight of 350 to 360 lb., containing a net electrode weight of approximately 300 lb. In the case of amorphous carbons, case sizes and weights will vary with electrode sizes.

Trade Usages

The requirements of the trade for both graphite and amorphous carbon electrodes vary between very wide limits. For this reason, the different electrode companies make no attempt to carry in stock all of the various sizes and shapes.

Carbon electrodes are manufactured in any size and shape desired. For ordinary use, the cylindrical or square shapes satisfy all requirements. Graphite electrodes may be obtained with any cross-section between the limits of $\frac{1}{16}$ in. to 12 in. in diameter and with any length up to 60 in.

The ease of machining graphitized electrodes is too well known to require any extensive discussion. They are easier to machine than the softest iron and may be finished with the same degree of nicety. Threads can be cut, holes drilled and tapped or the electrodes surfaced, sawed or shaped in any way desired by the use of ordinary wood-working tools.

The tendency in the industry is to make larger and larger electrodes to satisfy the requirements of electric furnaces, the dimensions and capacities of which are ever increasing. The largest single electrode which the industry has produced was made recently by the National Carbon Co. It is 24 in. in diameter, 180 in. long and weighs approximately 4,500 lb. If the demand existed this company is equipped to make electrodes up to 36 in. in diameter. Certainly, it is a long cry from Bunsen's first little sticks of carbonized wood to the mammoth high-density electrode of the present day! Bunsen's electrodes would float on water, the modern electrode has a density more than 1½ times that of water.

[26] See page 27 of "The Carbon Electrode," published by the National Carbon Co., Inc., New York, 1922.

Because of the inherent difficulty of manufacturing plates of great width by the extrusion method and the relative inferiority of molded plates for electrolytic work, it is often found much cheaper, as well as more convenient, to obtain wide electrode surfaces where necessary, by placing two or more graphite plates edge to edge and connecting them with graphite dowel pins.

Joining Electrodes

The desirability of using joined electrodes in any process is mainly a matter of calculation; the cost of power, the cost of electrodes and their length will decide the question. Offsetting the many advantages of continuous or joined electrodes are these disadvantages: (1) Machining operations (drilling, threading and tapping) increase the cost of the electrode. (2) The contact resistance between the portions of a built-up electrode causes loss of energy. (3) The joint is apt to loosen and to increase these energy losses, or the end of the electrode in the furnace may drop off, causing short circuits or other troubles.

On the other hand, the joint in a built-up electrode length serves as a very good thermal valve and lowers the thermal conductivity of the electrode, lessening the amount of heat conducted out through the electrode from the furnace.

In cases in which the furnace and the electrode holder permit the use of the electrode down to a small butt, in many cases it will be found more advisable not to join the electrode.

A good electrode paste is always used in practice to cut down the joint resistance losses. Experiment has shown that this joint resistance decreases as the electrode heats up and the paste dries or bakes. With the well-made electrodes the joint resistance, expressed in equivalent electrode length resistance, is very small.

The electrode manufacturers put up electrode pastes ready for use. They are usually thick suspensions of pulverized carbon or graphite in some medium that will be quickly volatilized by the heat at which the electrode is used. The chief difficulty with pastes is that precautions must be taken to prevent their drying out and hardening, after which they are almost useless.[27]

Economies and Economics

The complete flow sheet of electrode manufacture is introduced at this point to complete the discussion of processes. (See Fig. 42.) A glance will show that the industry loses practically nothing as waste and produces no byproducts. Green electrode scrap is re-used in process, gases from calcination are burned to heat the retorts to calcine additional material. Wherever possible, dust recoveries are made. Tar produced in the industry is used again as a binder; even producer gas soot from the soot legs is used as packing material. Recuperative and regenerative heating systems are the foundation of the present-day calcining retorts and baking furnaces. Scrap from the cleaning departments is re-used as unground calcined material; adhering packing material is recovered and carried back into process. The unconsumed portions of finished electrodes are sometimes used as raw materials. The circle is complete and endless.

Graphite electrodes cost three to four times as much

[27] For a very comprehensive discussion of the various methods of joining electrodes, the reader is referred to *Stahl und Eisen* for March 20 and April 3, 1913, translated into English in *Chem. & Met. Eng.*, June, 1913, p. 321.

TABLE I—COMPARISON OF AMORPHOUS AND GRAPHITIC CARBON ELECTRODES

	Acheson Graphite Electrodes	Amorphous Carbon Electrode*	Gas-baked Amorphous Carbon Electrode†	Large Elec ro-thermal Electrodes	Copper	Aluminum	Iron
Specific resistance (ohms per inch cube)	0.00032	0.00124	0.00161	0.00220	0 00000065	0.00000120	0.00000380
Specific resistance (ohms per cm. cube)	0.000813	0.00325	0.00400	0.00550

per pound or per piece as corresponding amorphous carbons. This might be explained by the fact that electrodes to be graphitized cannot be baked in gas-fired furnaces, which, it will be recalled, has been shown to be far cheaper than the electric method. In the second place, in order to graphitize a carbon article, several times as much power is used as would be needed to convert it into a good grade of amorphous carbon. By far the largest cost item in graphite electrode manufacture is the baking to graphitization.

The cost of any particular size of electrode to the trade will depend upon several factors: (1) The difficulty of forming that particular shape in the green. (2) The percentage of scrap normally resulting and necessary to reprocess. (3) The difficulty or ease of loading, baking and cleaning the particular shape and size. (4) The percentage of breakage, replacement and excess necessary to complete the order. In the case of both graphite and amorphous carbons the percentage of breakage during and after baking is a serious item.

Comparison of Amorphous and Graphitic Carbons

A comparison of the two forms of carbon of which electrodes are made, amorphous and graphitic, is given in Table I. Good graphitic electrodes have about one-fourth the resistance of good amorphous electrodes of the same size. The apparent density of graphite electrodes is usually two or three points higher than that of fine-grained petroleum coke electrodes. The tensile strength of amorphous carbons is about 50 per cent greater than that of graphitic carbons of the same diameter. It will be found that ordinarily graphite electrodes are much purer—that is, have a lower ash—inasmuch as almost all of the metallic and metalloid oxides were volatilized by the temperatures reached during the baking to graphitization. Copper, aluminum and iron are included in the table to permit of a comparison with carbon electric conductors. The comparative size of graphitic and amorphous carbon electrodes of equal ohmic resistance is shown in Fig. 45. Graphite and amorphous carbon electrodes are not competitors. The properties of each particularly fit it for distinctly different fields. The field of the amorphous carbon, used in large quantities, is that of electrothermal work, where the fact that its cost is only one-third to one-fourth that of graphite off-

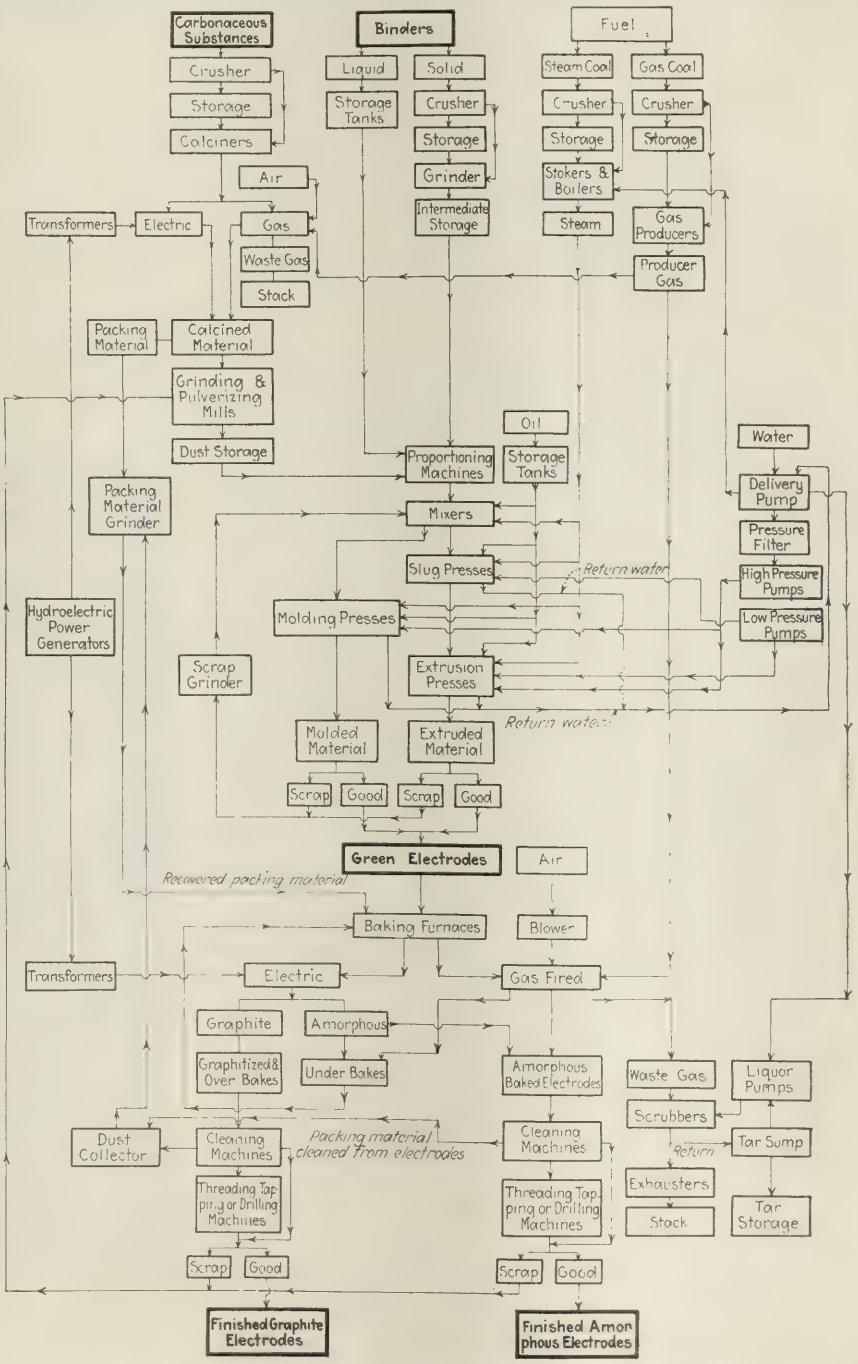

FIG. 42—FLOW SHEET OF CARBON ELECTRODE MANUFACTURE

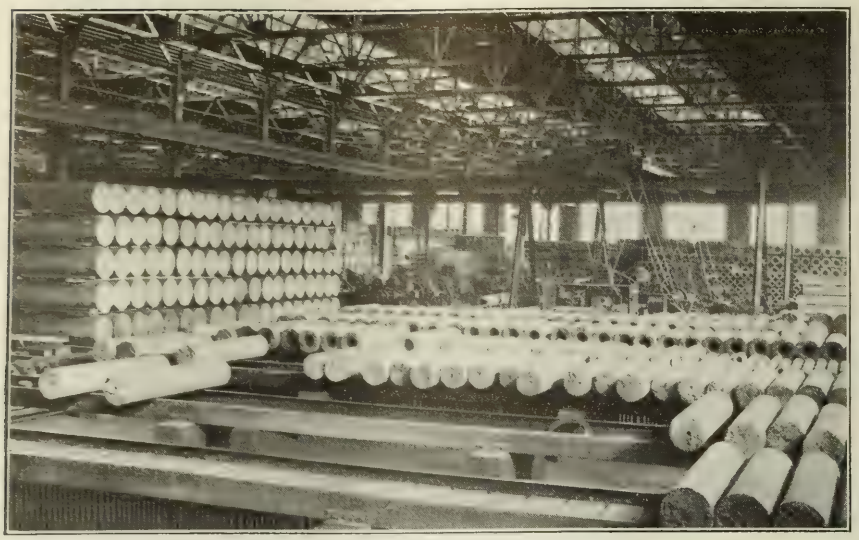

FIG. 43—THREADING AND INSPECTION DEPARTMENTS, NIAGARA WORKS, NATIONAL CARBON CO.

sets any advantages graphite might have. The particular field of graphite is that of electrolytic work, where its low resistance and long life are very important. Graphite electrodes are extensively used in the electrolytic production of chlorine and caustic, the chlorination of gold ores, the recovery of copper, nickel and zinc, the production of hypochlorites and many other similar applications.

Electrode Requirements

At the present time most of the carbon electrodes now manufactured are used in electrothermal work. In the United States, graphite has gained a well-deserved distinction for electrolytic work. In Europe, although graphite has also obtained due recognition, because of many adverse conditions amorphous carbon electrodes are still used in electrolytic work to a considerable extent.

For electrolytic work a low resistivity is both desirable and essential. In this case, low voltages and high amperages are used per cell. The higher the resistance of the electrodes the greater the voltage that must be applied to the cell and the higher the dead cost of electrolysis. With large currents even slight increases in resistance prove costly.

The apparent and real densities are both of importance. The first gives an idea of the porosity of the electrode, which to a certain extent is an advantage, inasmuch as it increases the active surface of the electrode, but if in excess, the bath liquid will enter the pores and cause a rapid generation of gas, which would tend to break off small chips, especially at the less porous edges. This would mechanically shorten the life of the electrode. An apparent density lower than 1.54 is undesirable, although from 1.4 to 1.6 is used.

Electrodes for electrolysis should not have more than 2.5 per cent of ash, and 4 to 5 per cent, as often found on the Continent, is distinctly disadvantageous. Higher ash content invariably means higher resistivity, with resulting electrical losses. The life of the electrode will suffer in consequence of the higher ash percentage.

In electrolytic work the electrodes are not consumed chemically or oxidized by surrounding air, but are eventually displaced through wear and tear. Impurities in the electrode do not therefore get into the cells in any great quantity through consumption of the electrode. In electrothermal work, however, the electrode is consumed largely by oxidation. The higher the apparent density the greater will be the amount of material packed in a given volume and the greater will be the length of time necessary to consume that volume. A carbon with a low apparent density offers a greater surface for oxidation per unit of weight than one with a high apparent density.

In summing up the requirements, it may be said that the following properties are necessary for the satisfactory performance of an electrothermal electrode:[27] (1) High electrical conductivity (low resistance). (2) Slow rate of oxidation (high apparent density). (3) Great mechanical strengths (particles well bonded together, suitable aggregate and thoroughly mixed). (4) Good shape and accuracy of dimensions. (5) Precise machining. (6) Low-heat conductivity.

Present and Future Developments

The Niagara Falls works of the National Carbon Co. was built in 1911. At the 1914 meeting of the American Electrochemical Society at Niagara Falls, that company exhibited a carbon 20 in. in diameter, 84

[28]Electrothermal electrode specifications may be found in "The Carbon Electrode," p. 34, published by the National Carbon Co. (1922), and "Operating Details of Electric Furnaces," by E. T. Moore, *Chem. & Met. Eng.*, vol. 24, No. 4, pp. 171-6, Jan. 26, 1921.

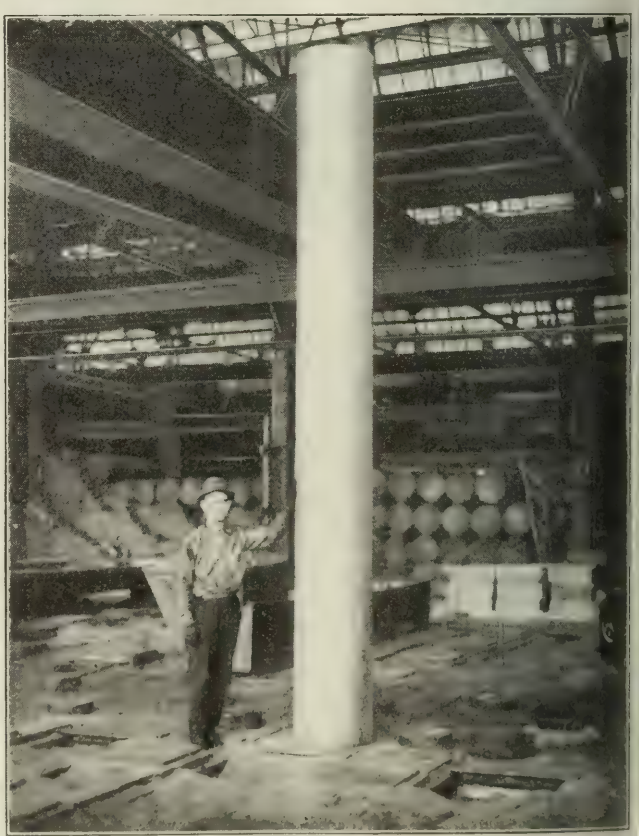

FIG. 44—ONE OF THE LARGEST ELECTRODES EVER MANUFACTURED. LENGTH 180 IN., DIAMETER 20 IN. WEIGHT 3,180 LB.

FIG. 45—GRAPHITIC AND AMORPHOUS CARBON ELECTRODES OF EQUAL RESISTANCE

in. long and weighing 1,450 lb. In 1921 the same company produced electrodes of larger diameter and 180 in. ong. Such has been the progress in the United States nside of less than 10 years.

While there have been many developments in the electrode industry in the past 10 years, the coming decade should bring forth even greater progress. It s possible here only to hint at some of the lines of development along which this progress will be made. Pitch coke is being developed as a raw material as a result of the possible shortage of petroleum coke. Probably there will be developed a tar or pitch still in which t will be possible to produce coke of such a fineness and of such a low content of volatile matter that the operations of calcining and pulverization will be unnecessary.

Developments along the line of the newer ring-type of gas furnaces have made possible the reduction of the cost of the baking process. The hydrocarbon gases generated from the binder in baking are used as fuel for heating sections of the furnace, thus making a considerable saving in producer gas. There have been some minor small developments along the lines of continuous electric furnaces (which is the superior but costlier baking method), with a view to recovering some of the enormous heat losses of radiation and cooling.

And last, but not of least importance, is the growing tendency for technical men in the industry to exchange information regarding the fundamental principles underlying the technology of carbon-electrode manufacture. Eventually this will result in greatly benefiting the industry as a whole and making it less and less of the "black art" which has characterized it in the past.

ACKNOWLEDGMENT

For their assistance in various ways in the preparation of this series of articles, the author wishes to acknowledge his indebtedness to W. H. Arison and Atwood B. Oatman, of the Acheson Graphite Co.; F. L. Zimmerman and C. S. Kinnison, of the Hoskins Manufacturing Co,; J. S. DeHart and J. A. Williamson, of the Isbell-Porter Co.; H. L. Goddard of the Jeffrey Manufacturing Co.; P. P. Huffard and his associates in the National Carbon Co.; W. A. Koren and S. B. Kanowitz, of the Raymond Bros. Impact Pulverizer Co.; John Robertson, of John Robertson & Co.; E. J. Smith and S. H. Farkas, of Edward J. Smith, hydraulic engineers, and finally, A. M. Redding, of the Leeds & Northrup Co.

For their kindly and helpful criticism of these articles, the author desires to thank F. J. Vosburgh and A. T. Hinckley of the National Carbon Co.

French Specifications for Impact Test

No particular type of testing machine or test-bar is specified by the French Committee on Standardization, but brief instructions concerning proper methods of testing are given below:

"The bar shall rest on bearers, 40 mm. apart, and shall be accurately placed before the blow is applied. The bearers shall have their upper surfaces rounded to a radius of 1 mm. A clearance in accordance with that shown in Fig. 1 shall be allowed in order to reduce friction at the extremities and to avoid the wedging of the bar.

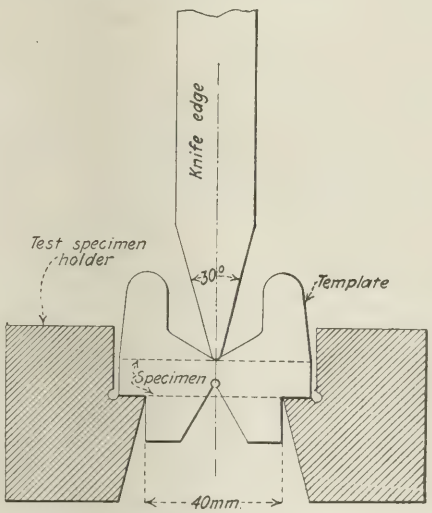

FIG. 1—TEMPLATE FOR LOCATING IMPACT TEST-PIECE

"The knife-edge fixed to the falling weight shall have a triangular section, the angle at the apex not being greater than 30 deg. The striking edge shall be rounded to a radius of 1 mm. It is absolutely necessary that the distance between the bearers shall be very frequently verified with a special template, and it is also necessary to insure that the knife-edge fixed to the falling weight is exactly in the middle of this distance.

"The position of the test specimen on the bearers must also be very carefully verified for each test with a special template, the position of the notch being taken into account. The speed of the blow shall not be less than 5 m. per second. Unless any figure is specially prescribed for the temperature, it shall lie between 15 deg. and 20 deg. C. The influence of the temperature is much more marked than in any other method of testing."

Two styles of test-bars are in use, the Mesnager and the Charpy. The former is 10x10x55 mm., notched 2 mm. by 2 mm. and round at the bottom; the Charpy bar is the same size, notched 5 mm. deep by a cylindrical hole 1.3 mm. in diameter and opened by a saw cut 1 mm. wide.

"Modification" of Aluminum-Silicon Alloys

By James J. Curran
Metallurgist, The Henry Souther Engineering Co., Hartford, Conn.

RECENT publication of articles on the alloys of aluminum and silicon has stimulated considerable interest in this subject. Three articles published within the last few months describe at some length the alloys containing from 5 to 15 per cent of silicon, and all call attention to the fact that alloys of this group may possess either one of two entirely dissimilar structures, spoken of as "normal" and "modified" or "refined." Some of the conditions under which either type of structure occur or may be obtained are stated by the various writers, who also remark on the superior tensile strength and elongation observed in alloys possessing the "modified structure. No reasonable explanation for the difference in structure and physical properties is suggested.

Previous to the appearance of these articles, the writer had occasion to examine a casting of "normal" alloy containing about 11 per cent silicon. This was a hydraulic casting and was stated to have withstood a hydraulic pressure of approximately 200 lb. without leaking, whereas the same casting made of the ordinary No. 12 aluminum-copper alloy leaked at 40 lb. pressure. This impervious state makes the alloy extremely desirable for hydraulic castings. More recently a sample showing the "modified" structure came to our attention, causing some speculation as to the reason for the difference in structure.

According to Jeffries[1], when the alloys were prepared by melting together commercially pure aluminum and silicon, the normal structure always resulted, whereas simultaneous electrolytic reduction of the two metals always produced the "modified" structure. This structure was also produced when the alloys were prepared by fusion of aluminum and a double fluoride of silicon and potassium (Wöhler's method), and alloys exhibiting the "normal" structure were converted to the "modified" form by fluxing with fluorides of the alkali metals.

[1]"Aluminum-Silicon Alloys," *Chem. & Met.*, April 19, 1922.

FIG. 1—STRUCTURE OF CASTING AS RECEIVED. "NORMAL." × 100. ETCHED WITH NaOH SOLUTION

All of these alloys, however, reverted to the "normal" form on remelting and holding in the molten condition for some time.

According to Guillet[2] and R. E. Search[3], the change in structure produced by the action of alkali fluorides on the melted alloys was ascribed to the removal of oxides, etc., or, in other words, simple fluxing.

The radical change in structure produced seemed to the writer to have a much deeper meaning than that ascribed, however. Examination of the historical data given in Jeffries' article indicates that the "modified" structure results only when alkali fluorides enter into the preparation of the alloy. For instance, the reaction between an aluminum-silicon alloy and NaF may form a small amount of Na and SiF_4. The SiF_4 formed is immedi-

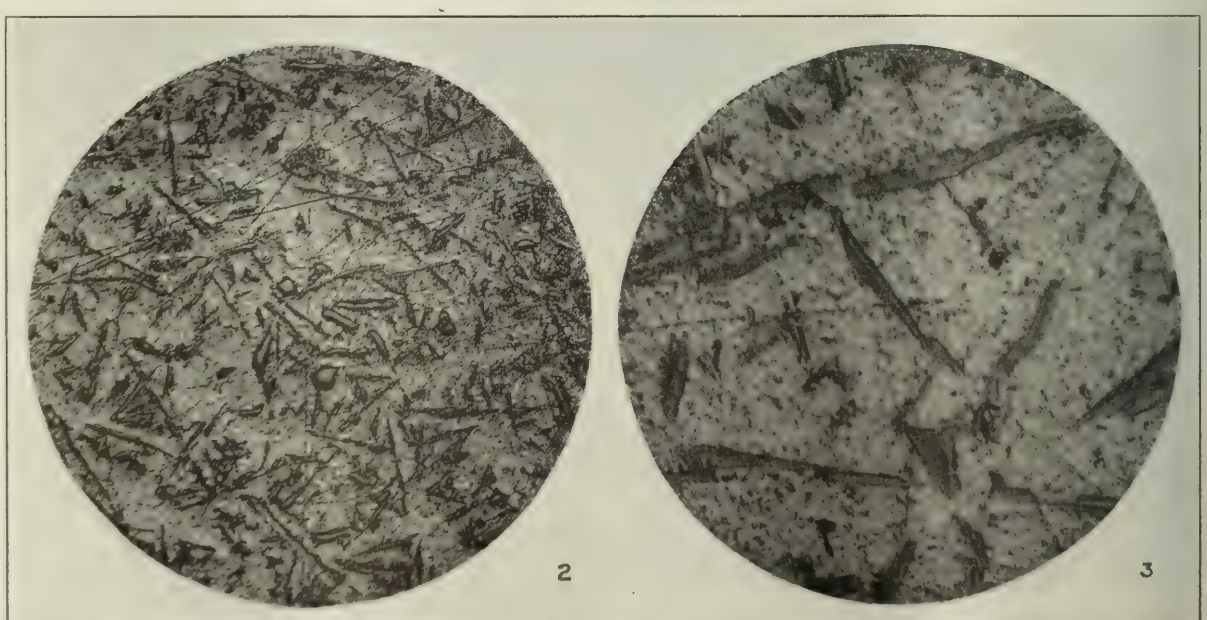

FIGS. 2 AND 3—STRUCTURE OF INGOT AFTER REMELTING. "NORMAL." × 100 AND × 500 RESPECTIVELY. ETCHED WITH NaOH SOLUTION

FIGS. 4 AND 5—STRUCTURE OF INGOT AFTER REMELTING AND ADDING SODIUM. "MODIFIED." × 100 AND × 500. RESPECTIVELY. ETCHED WITH NaOH SOLUTION

ately removed from the sphere of action, due to its gaseous state. The reaction takes place in a bath of aluminum which may be regarded as either a neutral or reducing medium or atmosphere, with the result that the Na produced cannot react to form any compound or salt, but is immediately dissolved in the aluminum.

It seems probable that alkali chlorides would give a similar reaction with evolution of $SiCl_4$, although it is possible that higher temperatures would be necessary. Other salts of the alkali and alkaline earth metals might also be selected to give similar effects under similar conditions.

If the alloy is prepared by simultaneous electrolytic reduction, we would expect a small amount of the alkali metal to be produced. This has been reported as a serious drawback to several of the early electrolytic methods of producing aluminum. Kahlenberg and Trautman (*Trans.*, Am. Electrochem. Soc., vol. 39) were apparently unable to produce the alkali and alkaline earth metals or silicides by reduction of their salts by silicon, although they quote Askenasy and Pounay as producing barium silicide by this means. Their failure was undoubtedly due to the fact that these metals, and probably also the silicides, oxidize rapidly in air. If the reduction were carried on in a neutral or reducing atmosphere, such as is afforded by a bath of aluminum, the results would have been different.

Remelting of a "modified" alloy—assuming it contained a small amount of alkali metals—would undoubtedly result in the elimination of the latter, thus explaining the reversion to "normal" structure noted by the writers quoted.

Having thus established a case for the alkali metals, the writer attempted to synthesize the "modified" alloy without the use of fluorides, as follows:

A casting possessing the "normal" structure shown in Fig. 1 and having the composition aluminum 88.32 per cent, silicon 10.72, iron 0.70, copper 0.16, manganese 0.01, carbon 0.09, was cut into small pieces, some of which were melted in a small crucible at a temperature of about 1,350 deg. F. The crucible was then removed from the furnace and the melt permitted to solidify in the crucible. The resulting alloy was then examined microscopically. The structure observed is shown in Figs. 2 and 3 at magnifications of 100 and 500 diameters respectively. This structure is characteristic for the "normal" alloy.

The remainder of the original casting was then melted as before in a small crucible at about 1,350 deg. F. and a small piece of metallic sodium was stirred into the metal, then the crucible was removed from the furnace and the melt permitted to solidify. Microscopic examination disclosed a characteristic "modified" structure—shown in Figs. 4 and 5.

Since the only difference in the preparation of the two melts was in the addition of sodium to the second melt, we believe that this is conclusive proof that the "modification" is caused by the absorption of sodium to form a ternary alloy. This would explain the failure of the "modified" alloys to behave according to the usually accepted binary aluminum-silicon diagram. No attempt was made to determine the amount of metallic sodium in the alloy, but its presence was indicated by an evolution of gas when the polished specimen was washed in water before etching.

In alloys for hydraulic purposes, resistance to corrosion is a very desirable property. The aluminum-silicon alloys are reported to be quite resistant to corrosion, and curves are given by Guillet in which one of the alloys is compared with others on the basis of resistance to corrosion. It is not stated definitely, however, whether the alloys were tested in the "normal" or "modified" condition. We would expect that the "normal" condition would show the greater resistance to corrosion and that the "modified" alloy, due to its content of alkali metal, would show inferior properties. The presence of small amounts of alkali metals caused rapid corrosion in aluminum produced in the early days of the electrolytic method, and one might expect similar results in the aluminum-silicon alloys, depending on the amount of alkali metal present. Comparison tests on the resistance to corrosion of the commercially prepared "normal" and "modified" aluminum-silicon alloys would therefore be instructive.

Commercial Furfural— Its Properties and Uses—II*

Part II of a Paper Describing the Rise of a Laboratory Curiosity to Industrial Importance — General Uses of Furfural — Complete Bibliography

By Carl S. Miner, John P. Trickey and Harold J. Brownlie
The Miner Laboratories, Chicago, Ill.

EARLY in the investigation of furfural, its property of discoloration was noted especially when exposed to light, the change taking place more rapidly in the anhydrous material than in the technical, which contains about 4½ per cent water. When technical furfural is distilled at atmospheric pressure to separate impurities, the color change in the purified product is quite rapid, changing in the course of a day from nearly colorless to a deep amber color. However, by using the method as given by R. Adams, this color change is retarded to a considerable extent. This method is briefly as follows: The technical furfural is distilled under diminished pressure (26 to 28 in. of vacuum) using a paraffine bath, the temperature of which is kept below 130 deg. C. At first water and furfural distill and separate in two layers. After about 15 per cent of the initial volume is collected the distillate coming over is pure furfural. The next 65 per cent is then collected as pure material. It should be stored in amber colored bottles.

Those who require a highly purified furfural for experimental work will obtain very satisfactory results by distilling technical furfural in accordance with the above directions just at or near the time it is desired for use.

Resins

Recently there has been an active interest taken in the manufacture of resins from furfural. Quite early in the history of furfural it was noted when working with the pure product or very concentrated solutions that instead of the desired reactions taking place, a tarry mass resulted. Stenhouse, in 1840, and Fownes, in 1845, in their earliest work on furfural, observed the formation of a brown resinous mass when furfural was boiled with alkali or acid. In 1887 L. Claisen attempted to prepare compounds from β-naphthol and furfural, using glacial acetic acid as the solvent and hydrochloric acid as the condensing agent. He obtained no well characterized compounds, obtaining only a brown resinous mass. No particular notice was taken of these products until the production of the phenol-formaldehyde resins became of commercial importance. Meunier (262) prepared a fusible, soluble resin by action of commercial aniline with an equal part of furfural in presence of alkalis. The product was a black resin, soluble in benzene and alcohol, giving a black enamel. Beckman and Dehn (261) made a rather extensive investigation of the condensation products of furfural with the phenols. They reported on the products obtained from 24 different phenolic compounds. They obtained their best results with phenol, raw cresol, guiacol, carvacrol and β-naphthol, using 5 per cent of hydrochloric acid as the condensing agent and equal parts furfural and the phenol.

Their work using basic catalyzers such as sodium carbonate, sodium hydroxide, etc., seemed to show that the reaction as well as the final product was not as desirable as the acid resins. In the experience of the authors this is at variance with the facts, as in our experience the alkali resins are much more easily controlled and the final product much superior to the acid resins. A paper is being prepared covering our work on these resins.

Mains and Phillips (258) prepared a series of resins from furfural with amines. In all cases they were fusible and soluble, the solutions forming excellent enamels.

Quite recently Novotny has patented a process for preparation of phenolfurfural resins using both furfural and furfuramide in its preparation. These are molding resins forming hard, infusible, insoluble products. We are informed that molding resins now are being successfully prepared on a commercial scale from furfural.

Varnish

Besides the preparation of the fusible, soluble resins which may be used as varnish resins, investigations have been made which seem to show the applicability of furfural either alone or in admixture with oil of turpentine in the preparation of varnishes. Claim is made of a much lower acidity than in the common methods of varnish manufacture.

Rubber

Some work has been done on the use of furfuramide in the rubber industry as a substitute for hexamethylenetetramine. The results of this work show some promise of its adaptability. It has been found to have decided accelerating effects. Further work is being done on this phase of its application.

Dyes

Practically all of the compounds reported on in the section of this paper devoted to the chemistry of furfural which are formed by the action of furfural on aromatic amines are either highly colored compounds or become so by oxidation. Many of these have decided staining or dyeing properties and in the light of recent investigations furfural gives promise of becoming of importance in the preparation of commercial dyestuffs.

Anesthetics

Dr. Gilman, at the Birmingham meeting of the American Chemical Society, reported on the preparation of an anesthetic from furfural. This opens up an entirely new field in the application of furfural.

Antiseptics and Germicides

Furfural has decided antiseptic and germicidal properties, as is brought out by the work of McGuigan. The authors of this paper studied the effect of furfural on the keeping qualities of bacteria infected glue. They found that glue that "went bad" in 18 to 24 hours after

*Part I of this article, describing the occurrence, manufacture and properties of furfural appeared in *Chem. & Met.*, vol. 27, No. 7, Aug. 16, 1922.

placing in solution would keep for several days when the solution was made in a 1:500 furfural:water solution, and that the solutions would keep for several weeks when made in a 1:250 furfural:water solution.

Solvent

The authors have under way an investigation of the solvent action of furfural. Among the interesting data developed to date are the facts: that furfural is an excellent solvent for both nitrocellulose and the hydrated cellulose acetates; that while linseed oil is very slightly soluble in furfural, chinawood oil is miscible in all proportions; that stearic acid is quite soluble in hot furfural, but is only soluble to about 1 part in 50 at 25 deg. C., while oleic acid is readily soluble at 25 deg. C.

Larger production and increased efficiency of manufacturing process will make possible the reduction in the price of furfural to a point where it can compete on a parity, or better, with formaldehyde and the high boiling point solvents. In view of the many possibilities of commercial utilization already indicated, it seems highly probable a vastly greater number of profitable methods for its use will be developed. Since it can be made from any of the pentosan-bearing roughages now either wasted or sold at extremely low price, it seems reasonable to predict that a considerable percentage of those millions of tons of what is now virtually waste material will ultimately form the basis of a new industry of enormous proportions.

Magnetic Analysis of Metal

In any study of the physical properties of materials the effect of temperature is of great importance. It is well known that at a certain temperature ferromagnetic materials lose their ferromagnetic properties and become very feebly magnetic. It is not so well known, however, that certain more or less abrupt changes in magnetic properties take place at lower temperatures during heating and cooling and that these changes are often indicative of structural transformations in the material. The Bureau of Standards has designed and constructed apparatus for the purpose of investigating these phenomena. Little work of this nature has been done in this country, although valuable results have been obtained by this method abroad, especially by Japanese investigators.

Endurance Studies on Alloy Steel

Dr. H. W. Gillett, at the Ithaca station of the Bureau of Mines, has embarked upon an extensive program of endurance tests, using molybdenum and other alloy steels. About 600 test-pieces have been prepared, and two testing machines will be kept constantly in operation.

A New Tiering Truck

THE tiering truck equipped with electric motor and storage battery has a wide field of possible utility. It would have met with much greater favor from industry in general in the past, except that the models offered had certain defects of design which tended to curtail their usefulness. Many industries that could have effected real economy by using tiering trucks have held off making purchases of this type of equipment until one was offered which they considered dependable.

For this reason the "Eleveyor," a tiering truck recently placed on the market by the Electric Industrial Truck Co. of Brooklyn, N. Y., is considered noteworthy.

FIG. 1—ELEVEYOR WITH PLATFORM LOWERED

The makers of this truck claim to have eliminated numerous disadvantages found in some of the older models. One of the principal improvements claimed for the "Eleveyor" is in the design of the frame. This frame, as shown in the accompanying photographs, is made of structural steel throughout and is so designed as to increase greatly the strength and stability of the truck. Another advantage lies in the elimination of parts and in the unobstructed dash and operators step which results from this.

One of the chief features of the truck is the use of standard equipment, largely that developed in the automotive industry, wherever possible. The differential is a Brown-Lipe-Chapin. The main drive is through a Morse silent chain. All bearings are standard SKF deep grove ball bearings. The hoist is a triplex-geared chain hoist, operated by a G. E. motor. The driving motor is also a G. E. motor. The main controller is a G. E. heavy duty drum-type controller, so designed that the necessity of the "safety" switch found on most other designs of truck is eliminated, thus saving many adjustments and complications.

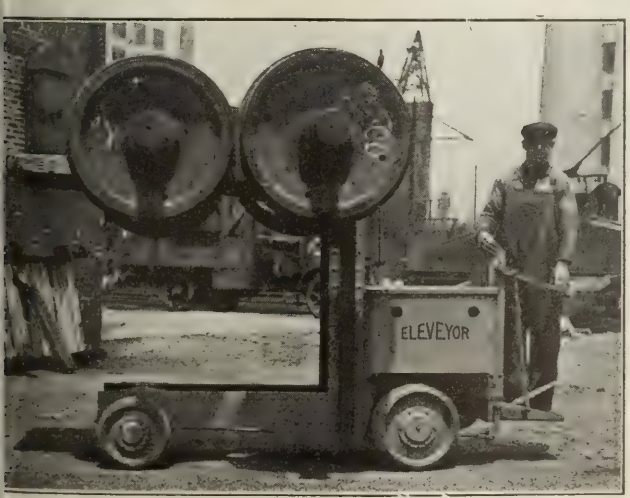

FIG. 2—ELEVEYOR WITH PLATFORM RAISED

One of the new departures presented in this truck is the use of a chain hoist for elevating the platform. A chain hoist is constantly engaged, so that the load is safely held at all times. Its mechanism possesses great strength, few parts and high efficiency and is felt to be superior to gear train, planetary system, cable, or screw such as has been used in former designs of tiering trucks.

A summary of the advantages claimed for this truck comprises the following:

1. Exceptionally large platform and wheels.	For bulky material and rough roadways.
2. Platform spring suspension.	Relieves load and frame from injurious shocks.
3. Platform track construction.	Provides great strength and a short truck.
4. Parallel link drive axle suspension.	Provides ideal spring action with simplicity.
5. Battery compartment free of all overhead obstruction.	Battery easily watered or removed.
6. Shortest possible truck length for a given size platform.	Turns in close places.
7. Most efficient gearing in transmission and hoist.	Operates longer with given battery capacity.
8. Neutral return controller.	Facilities starting on a grade and keeps driver's hand on lever.

A New Pipe Wrench

Those who have had anything to do with plant construction or operation are likely to be familiar with the "Little Giant" line of screw plates, taps and dies. The Greenfield Tap & Die Corporation, of Greenfield, Mass., has recently added to this line the "Little Giant" pipe wrench, a cut of which is here shown.

This wrench is of the end opening type, like the familiar machinists' wrench. It is claimed that this construction makes the new tool particularly applicable to use in corners and other confined places.

Among the advantages claimed for this wrench are the small number of parts, there being only three; the unusual strength, combined with light weight; and the double set of teeth on the main jaw, which doubles the life of the tool.

This wrench will be made in 8, 10, 14, 18 and 24 in. sizes, the three smaller sizes being now procurable.

Book Reviews

THE PRINCIPLES OF ORGANIC CHEMISTRY. By *James F. Norris.* Second edition, 632 pages. New York: McGraw-Hill Book Company, Inc., 1922. Price $3.

There has been a tendency among authors of college text-books of chemistry to expand them into volumes of formidable size, and the reviewer feels that Professor Norris is to be congratulated on resisting this temptation.

The book contains about fifty pages more than the earlier edition, but the new matter which has been included will certainly add to the student's interest in the subject. The author has not hesitated to include a brief description of industrial processes as frequently as could be expected in an elementary work of this kind. Among the new subjects included, the reviewer notes the manufacture of isopropyl alcohol from petroleum still gases, some notes on the manufacture and toxicity of phosgene and its use as a war gas, a brief description of mustard gas and its methods of preparation, a brief reference to the Bucher process, the catalytic oxidation of benzene to maleic anhydride, the manufacture of ethylene glycol from ethylene and the intermediate ethylene chlorhydrin.

The chapter on dyes has been somewhat extended, and the chapter on proteins has been amplified and brought up to date as far as is consistent in a book of this kind. It is inevitable that the subject matter included in a text-book of this kind will be nearly identical with other books of the same scope and purpose. The quality which distinguishes works of this kind is the clearness of the exposition and in this particular case the interjection of many statements which cannot help but impress upon the mind of the student that the science of organic chemistry is a live, growing subject, not a dead one. There is a dynamic quality in this work of Professor Norris' which is difficult to inject in a work of this kind. It reflects the art of an extraordinary expositor.

B. T. Brooks.

PROTEINS AND THE THEORY OF COLLOIDAL BEHAVIOR. By *Dr. Jacques Loeb.* New York: McGraw-Hill Book Co., 285 pp. 1922. Price $3.

Besides presenting in convenient and coherent form his ingenious and extensive researches on proteins (chiefly gelatine, albumin and casein) which have appeared in journal articles over a long period, the author in this book gives many hitherto unpublished experiments to support his views.

The first part of the book "furnishes proof of the stoichiometrical character of the reactions of proteins"; the second part gives a "theory of colloidal behavior based on Donnan's theory of membrane equilibria." "Any rival theory which is intended to replace the Donnan theory must be able to accomplish at least as much as the Donnan theory—i. e., it must give a quantitative mathematical and rationalistic explanation of the curves expressing the influence of hydrogen-ion concentration, valency of ions and concentration of electrolytes on colloidal behavior and it must explain these curves not for one property alone but for all the properties, electrical charges, osmotic pressure, swelling, viscosity and stability of solution, since all these properties are affected by electrolytes in a similar way."

But "such an application of Donnan's theory would have been impossible without the stoichiometrical proof that proteins form true ionizable salts with acids and alkalis. What was at first believed to be a new type of chemistry—namely, colloid chemistry—with laws different from those of general chemistry, now seems to have been only an unrecognized equilibrium condition of classical chemistry; at least as far as the proteins are concerned. This does not detract from the importance of colloidal behavior for physiological and technical problems, but it completely changes the theoretical treatment of the subject." Evidently then, as the title indicates, Loeb accepts colloids and offers a theory of their behavior. His book should be read by all interested in the subject.

Because of the high reputation of the author, many scientists will be prone to accept his conclusions without submitting his experiments and arguments to critical examination. Your reviewer feels constrained therefore to point out what appear to him to be some basic errors, both experimental and rational, which strike at the very root of Loeb's conclusions.

Loeb's whole thesis is based on the formation of true ionizable protein salts—e. g., gelatine chloride and sodium gelatinate. This naturally assumes that gelatine is a definite chemical entity, which no one has ever demonstrated. In fact the existing evidence is to the contrary. Thus, the analyses of Levene, Skraup and von Biehler, Dakin, Bogue and others differ widely. But Loeb has failed to define exactly the *quality* of the gelatine he has used. He describes it (p. 35) as "commercial powdered Cooper's gelatine, which happened to have a *pH* of 6.0 to 7.0," but before using it he brought it to the isoelectric point and purified it by treatment with M/128 acetic acid. Nothing is stated of the percentage of gelatoses or of gelatones in the purified product, nor is the jelly-strength or mutarotation (after C. R. Smith) given, from which a rough idea of their percentage might be formed. The gelatine apparently lost 20 to 25 per cent during purification, which introduced a like error into some of Loeb's earlier experiments. (See e. g. Harvey Society address, *Science*, N. S., vol. 52, p. 451 (1920); *J. General Physiol*, vol. 3, p. 89 (1920); also the present book, (p. 58).

Again Loeb has failed in each case to define exactly the ash and moisture content of the gelatine used, both being essential (especially the latter) in fixing the percentage of gelatine in solution. C. R. Smith, *J. Am. Chem. Soc.*, vol. 43, p. 135 (1921) and Miss A. M. Field, *ibid.*, vol. 43, p. 667 (1921), had shown how to prepare ash-free gelatine, which is by no means identical with isoelectric gelatine. Loeb gives (p. 35) "a result of an ash determination made by Dr. D. I. Hitchcock on a sample of gelatine selected at random" from one of Loeb's stock solutions containing 12.69 per cent gelatine. The analysis showed about 0.1 per cent ash, apparently $Ca_3(PO_4)_2$. Loeb says this amount of ash is without influence, but since C. R. Smith has shown that Ca may exert a powerful influence, it would have been better had Loeb determined the ash of every specimen of gelatine the ash of *every* specimen of gelatine he actually used. The paper of Oakes and Davis (*J. Ind. Eng. Chem.*, vol. 14, p. 706, 1922) also shows the importance of "ash."

Loeb's experimental results are reported mainly in curves or graphs which your reviewer believes are incorrectly plotted and drawn. This is quite evident in the graphs of Chapter VI, where *equal* increments on the axis of abscissas are given M/2, M/4, M/8, M/16, M/32, etc. It is not so obvious in the other chapters where equal increments are given *pH* values of 1, 2, 3, 4, 5, 6, 7, etc., because most readers do not stop to consider the real meaning of *pH*. This abbreviation of Sorensen is an inverse logarithmic value deprived of its minus sign. The following table will give an insight:

pH value	Number of Times the H (or OH) Ion Concentration Exceeds That of Pure Water
1	1,000,000
2	100,000
3	10,000
4	1,000
5	100
6	10
7	i.e. conc. H and OH = 10^{-7} mols per liter. . . . . 0 (pure water)
8	10
9	100
10	1,000

Thus, decrease in *pH* value means increase in acidity, not in an arithmetical but in a logarithmic ratio. Curves plotted on an arithmetical basis, as are Loeb's, are thus logarithmically compressed and deviations there appearing as experimental errors may really obscure cusps or inflections. Loeb's method of plotting is furthermore apt to make the reader forget that values of about *pH* 6 to *pH* 7 represent an extremely slight acidity. *N*/10 HCl has a *pH* = 1.07 and ordinary distilled water in the laboratory (containing CO_2) has a *pH* = about 5.5.

Therefore values of about *pH* 2 to *pH* 3 represent a very high acidity. Curves which Loeb shows with equal branches, resembling parabolas, should rise sharply, almost asymtotic

to the *pH* 4.7 ordinate, and after turning, gradually approach to axis of abscissas. Some other points may be epitomized as follows:

The view (Chapter II) that proteins fix acids by their free NH_2 groups and acids by their free COOH groups, while simple, does not accord with the observation that deaminized gelatine (Blasel and Matula) and highly hydrolyzed gelatine (T. B. Robertson) both fix about as much acid as the original gelatine. Jordan Lloyd and Mayes (*Proc. Roy. Soc.*, B. vol. 93, p. 39, 1922) give additional evidence that disproves this appealing but incorrect chemical explanation.

Loeb's interesting qualitative experiments (Chap. II) show, as Bancroft remarked, that acid or plus-charged gelatine (*pH* less than 4.7) fixes only anions, while alkaline or minus charged gelatine (*pH* less than 4.7) will fix only cations, which is only to be expected. Clay or fine silica might act similarly.

His quantitative experiments (Chap. V) show e. g. that the number of c.c. of different *N*/10 acids required to bring isoelectric gelatine to the same *pH* varies roughly in accordance with the *pH* (available or effective acidity) of each acid at that *pH*. Thus at *pH* 3 the effective acidity of HCl and H_2SO_4, oxalic, and phosphoric acids are about 3, 2 and 1 respectively and Loeb found that to bring one gram of isoelectric gelatine to *pH* 3, it took (in c.c. of *N*/10 acids) 7.2 HCl, 7.5 H_2SO_4, 13.15 oxalic, 20.7 phosphoric. Most of his experiments stop at about *pH* 2, which represents an acidity equal only to *N*/100 HCl (*pH* 2.02).

Assuming that deviation from the curves is due only to experimental errors, these results, while not inconsistent with the view that chemical compounds have been formed, may simply be due to the fact that within the *pH* range of the experiments, gelatine has, at each *pH*, a more or less definite free adsorptive surface and adsorbs acids in proportion to their free field of force. The fact that material chemical changes (see above) in gelatine do not affect its acid combining capacity appreciably favors the adsorption rather than the chemical view. Even W. B. Hardy (see Loeb, p. 9), who utterly expressed belief in salt formation, stated that the reactions are not precise. No one has ever prepared chemically pure gelatine, and estimates of its combining weight vary from about 768 (Proctor and Wilson) to about 96,000 (C. A. Smith). Jordan Lloyd gives chemical evidence that it cannot be less than about 10,300 and Loeb apparently believes it to be between 12,000 and 25,000. As Hardy indicates, it depends upon conditions, and your reviewer believes it will also vary with the kind of gelatine. It is still to be demonstrated that these compounds possess the definiteness which is at present connoted by the expression "chemical compound."

The *pH* (that is, the effective reaction) of acids is controlled by the specific nature of their anions; the *pH* of alkalis by the specific nature of their cations. The *pH* of *N*/100 HCl is 2.02, but the *pH* of *N*/100 acetic acid is 3.37. Why? Because in aqueous solution Cl releases H+ more readily than does CH_3COO-. This means that HCl is a strong acid and acetic a weaker one.

Hofmeister, Ostwald and M. H. Fischer observed the effect on proteins, of *equal molar concentrations* of various acids and alkalis and then compared the consequences of their *differing pH or effective reaction.* Loeb, on the other hand, uses enough of various acids and alkalis to make their *effective reactions* (*pH*) *equal* and then compares the *varying quantities required.* What he considers "practical identity"—e.g., in curves of Figs. 19 and 20 (pp. 79 and 80)—may appear differently if the curves are correctly plotted. He even comments (p. 80) on the anomalous behavior of acetic acid, probably caused by sol formation (see below).

That the problem of the swelling of gelatine in acids is not as simple as a Donnan equilibrium formula would indicate is evident from the work of A. Kuhn (*Kolloidchem. Beihefte*, vol. 14, p. 202, 1921), who found it to be dependent upon four factors:

A (*1*) Hydration (simple swelling)
B (*2*) Sol formation (incidental peptization)
(*3*) Hydrolysis
C (*4*) Dehydration (flocculation)

The maximum is reached when, with increasing concentration of acid, hydration is overbalanced by sol formation and hydrolysis. Probably it was sol formation that caused Loeb to lose about 20 per cent of his gelatine in his earlier experiments (p. 58). Since sols (as Graham distinctly pointed out) do diffuse, albeit though slowly, we have here another factor working contrary to the Donnan equilibrium. Experimenting with 50 organic acids, Kuhn could not decide if the combination was chemical or adsorption.

Loeb argues (p. 16) that "if the addition of a salt to a protein solution diminishes its osmotic pressure by causing an increased formation of aggregates, the same addition of salt should increase the viscosity of such a solution. The reverse, however, happens, the viscosity of the solution being decreased by the addition of salt." Loeb here entirely overlooks the existence of the zone of maximum degree of colloidality. (See *J. Am. Chem. Soc.*, vol. 43, p. 434, 1920.) Viscosity does often increase as particles aggregate, as in cooling gelatine solutions, but viscosity may also increase as particles are dispersed, as when cream is homogenized, or karaya gum dispersed.

Loeb makes the sweeping assertion (p. 278) that "there is only one source of colloidal behavior—namely, the Donnan equilibrium—at least as far as the proteins are concerned." Donnan can hardly believe this, for Loeb quotes him (p. 22) as saying (*J. Chem. Soc.*, vol. 105, p. 1963, 1914) that in the comparatively simple case of a copper ferrocyanide membrane and potassium ferrocyanide solutions, "the phenomena are not so simple as supposed in the theory." The great danger of applying mathematics to chemical and physical problems lies in the fact that we may be blinded by the logical perfection of this mere tool and make erroneous assumptions, or else neglect important factors which so often crop up unexpectedly in nature. The fact that some of the assumptions involved in Donnan's equations do not apply to gelatine has been pointed out by Jordan Lloyd—e.g., the gelatine "ion" does diffuse. The basic assumption that a true hydrolyzable "salt" is formed is, to say the least, doubtful.

A word in defense of Thomas Graham is necessary, for his classic papers are seldom consulted in the original. Loeb states (p. 275): "Graham had suggested the distinction between colloidal and crystalloidal substances, but it was found later that one and the same substance—e.g., NaCl, may behave when in solution either as a crystalloid or a colloid. It was then proposed to drop the distinction between colloidal and crystalloidal substances, and distinguish between the colloidal and crystalloidal state of matter." This is surprising, for Loeb on page 1 quotes from Graham the very paragraph wherein the word "colloid" was born; the particular sentences of Graham are: "As gelatine appears to be its type, it is proposed to designate substances of the class as colloids and to speak of their peculiar form of aggregation as the colloidal condition of matter. Opposed to the colloidal is the crystalloidal condition. Substances affecting the latter form will be classed as crystalloids. The distinction is no doubt one of intimate molecular constitution." Further on in the same paper, "Liquid Diffusion Applied to Analysis" (1861), Graham says: "The mineral forms of silicic acid, such as flint deposited from water, are often found to have passed during the geological ages of their existence from the vitreous or colloidal into the crystalline condition (H. Rose). The colloidal is in fact a dynamical state of matter, the crystalloidal being the statical condition." And still further: "The inquiry suggests itself whether the colloid molecule may not be constituted by the grouping together of a number of smaller crystalloidal molecules and whether the basis of colloidality may not really be due to this composite character of the molecule." So Graham did know that the same substance can exist in both colloidal and in crystalloidal state. Modern research has fixed dispersion into particles between about 100 $\mu\mu$ and 5 $\mu\mu$ as the criterion of the colloidal condition, and the particles may be crystalline or consist of random clusters. But these statements of Graham still hold true.

It is to be regretted that Loeb did not review, discuss and consider the results of many important workers in

this field. Thus he does not mention Blasel and Matula, Arisz or Jordan Lloyd and dismisses C. R. Smith with mere mention in a footnote (p. 36) and Wo. Ostwald and Martin H. Fischer in a brief quotation from Zsigmondy (p. 76). He quotes and demolishes Pauli, with whom Ostwald and Fischer likewise disagree. All told, Loeb's book is written from the standpoint of an advocate pleading his cause, rather than from that of a judge deliberately weighing all the evidence, and this brings inherent weakness. JEROME ALEXANDER.

American Patents

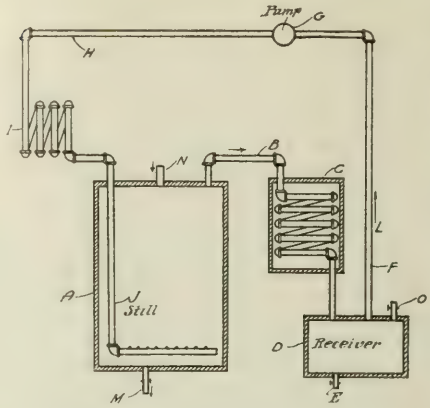
Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Tar Distillation—In the distillation of tar, the progressive decomposition which takes place results in the formation of "free" carbon and pitch. The greater the amount of these products formed the less the amount of tar oils recovered and hence, the less the value of the products. For the purpose of assuring the highest possible yield of these more valuable tar oils, John M. Weiss of New York has invented the distillation method shown in the accompanying drawing.

The basis of this process is the agitation of the tar during distillation with a large amount of some gas chemically inert toward tar and containing little if any oxygen. The gases available include nitrogen and CO_2, which are the principal constitutents of air after the oxygen has been used. This type of agitation has been found to increase the oil yield materially.

For best results an amount of gas not less than 1 cu.ft. (measured at ordinary temperatures and atmospheric pressure) per minute per 100 gal. of original material introduced in the still should be recirculated and an amount greater than 20 cu.ft. per minute per 100 gal. of original material to be distilled does not seem to present any substantial advantage in obtaining a higher yield of oil than the lesser amounts. The gas should also be heated before being introduced into the still.

As illustrative of how the process can be applied to tar-distillation reference may be made to the appended illustration. A still *A* heated by any suitable means and provided with a drawoff *M* and a filling line *N* is connected by a pipe *B* to a condenser *C*, which delivers into a receiver *D* with a drawoff *E*. From the top of the receiver a pipe *F* leads to a pump *G* and thence by a pipe *H* to a superheater *I* and by the pipe *J* to the bottom of the interior of the still communicating with it through a perforated pipe. The inlet pipe *O* serves as a vent or for the introduction of gas into the system. The arrows *L* show the direction of gas flow.



The still is charged with the tar to be distilled and the pump *G* started and a suitable gas is drawn in through pipe *O* until the system is filled. The system is then closed and heat applied, the gas being circulated at the desired rate. Distillation starts and is continued with the circulation maintained until the residue in the still is of the desired consistency, the volatile constituents being carried off by the circulating gas from still *A* and condensed in the condenser *C*. The heat and gas circulation are then discontinued and the residue is removed from the still *A*.

The following results illustrate the advantage which may be obtained by the use of this process in the distillation of a byproduct coke-oven tar. The particular tar used had a free carbon content of 8.5 per cent. Passage of gas in all cases was made at the rate of about 15 cu.ft. per minute per 100 gal. of material introduced in the still.

	Per Cent by Wt., Oil Obtained	Per Cent by Wt., Pitch Obtained,	Pitch Air Melting Point, Deg. F.	Pitch per cent Free Carbon
Distillation without agitation	40.1	57.8	280	40.7
Air used not recirculated	33.0	63.0	286	35.1
Nitrogen recirculated	52.0	46.4	277	27.2
Carbon dioxide recirculated	51.2	46.7	270	28.2
Mechanically stirred	40.0	57.9	300	46.5

(1,418,893—John M. Weiss, assignor to The Barrett Co., June 6th, 1922.)

Retort—In many manufacturing operations where retorts, furnaces and the like are subjected to a high temperature it is desirable to employ iron or other similar relatively cheap and plentiful metal as the retort or furnace material. For example, in the manufacture of coal gas, oil gases and in certain processes employed to effect the fixation of atmospheric nitrogen, iron retorts or furnaces would be highly desirable were it not for the fact that corrosion is quite rapid at the high temperatures required in these processes. The rapid deterioration and destruction of retorts or furnaces consisting of iron or other similar metal involve in many cases a prohibitive maintenance cost and a consequent or necessary elimination of iron as a furnace material for such purposes.

This invention consists in coating the iron or other cheap basic material with a coating which offers substantial resistance to the corrosive action of the gases generated. In this way the life of the retort is greatly prolonged, and the upkeep expense appreciably reduced. An alloy of nickel and chromium in the proper proportions with or without the addition of smaller quantities of other metals serves as a protective coating for the iron retort or furnace. Such an alloy may consist of 85 per cent nickel and from 10 to 15 per cent chromium, the variations in the latter depending upon the amount of impurities which may be present such, for example, as iron, manganese and carbon. This alloy should be sprayed on the base metal in a molten state or coated on in some other form so that a uniform, dense and compact coating is formed over all surfaces of the retort. (1,422,878; Floyd J. Metzger, of New York, N. Y., assignor to the Air Reduction Co., of New York. July 18, 1922.)

Refractory Silica Brick.—It is a well-known fact that ordinary refractory silica bricks show a tendency to swell or expand when used in high-temperature furnaces, this gradual increase in volume resulting in disintegration and destruction of the furnace structure. In the endeavor to do away with this disadvantage, it has been discovered that a long-continued baking process at a temperature approximately 1,400 deg. C. obtains at least the partial transformation of the quartz in the brick material into tridymite and results in the production of a brick of approximately constant volume. This process is expensive, however, and the present invention is offered as a cheaper and surer way of accomplishing the same end.

In this process, small quantites of a phosphate or similar material such as boric, tungstic or molybdic acids or their salts are introduced during the process of mixing the quartz with the clay cement or lime. If, then, the brick is heated to a temperature of about 1,300 deg. C. for about 8 hours, it is found that most of the quartz is transformed into allotropic forms of lower specific gravity.

It is claimed that in this way refractory silica brick may be manufactured from quartz which will have substantially constant volume under high temperatures. (1,420,284; Orazio Rebuffat, Naples, Italy, assignor to Pomilio Bros. Corporation, New York. June 20, 1922.)

Gas Producer—The producer is a downwardly widening chamber provided at the base with a steam-generating space located laterally or in an annular ring above the lower section of the combustion chamber. The air for combustion is so directed past the outlet of this steam-generating chamber as to carry moisture into the fuel bed with it. The object sought is durability of construction and higher gas production efficiency because of the generation of small quantities of water gas mixed with the producer gas. (1,414,109; F. M. E. Blass. April 25, 1922.)

Last Minute Changes in Tariff Bill Boost Items on Chemical Schedule

enate Passes Fordney-McCumber Bill by Vote of 48 to 25—Bursum Amendment Replaces Dye Embargo—Flexible Provision Extends to 1924

WHEN the Senate concluded its consideration of the tariff bill in ommittee of the whole and took up the easure in the Senate proper, no fur- er vote on the chemical embargo ature of the bill was taken. This was ue to the fact that the necessary votes reverse the decision reached in the mmittee of the whole could not be unted. Apparently three votes were cking to insure the adoption of the nbargo. It then was decided that the ursum amendment would be the next st thing and the friends of the chemi- l industry reluctantly decided not to sk another roll call on the embargo.

Some are of the opinion that the ursum amendment is preferable to an nbargo, since it will last through the e of the act and obviates the necessity making the whole fight over again at e end of the year.

While the average of the specific tes are admittedly high in the bill as whole, Chairman McCumber of the inance Committee contends that the erage ad valorem rates are lower an in any Republican tariff bill acted heretofore. The Senate ma- rially reduced the rates prescribed in e House bill, with the exception of ose on coal-tar products and those in e agricultural schedule. These rates re increased materially.

Flexible Provision

One of the very important phases of e bill is its provisions for flexible riff. This is the first time any asticity in tariff rates has won the proval of either house. While the endment proposing to enlarge the riff Commission did not prevail, the mmission is authorized to hold hear- gs and to conduct continuous investi- tions with the idea of remedying any equities that may be found in tariff tes. The Tariff Commission will sub- t its finding of facts to the President, o is empowered until July 1, 1924, to ange rates, provided that no change, her up or down, is to exceed 50 per nt. The date of July 1, 1924, was se- ted by the majority party so that in e event of a change of administration e power would not be conveyed to a mocratic President.

The most drastic change made by the nate in the tariff bill came in the al week when an amendment pro- sed by Senator Bursum of New Mexico was accepted, increasing the rates of duty on coal-tar products and changing the basis of valuation on these dyes and chemicals from foreign to American.

Acceptance of the Bursum amendment in the committee of the whole was by a vote of 38 to 23 and this action was sustained by a vote of 39 to 31 when the bill was reported to the Senate proper. This is in contrast to the vote of 32 to 38 by which the proposed extension of the dye embargo failed of approval July 15.

Dye Rates Increased

The Bursum amendment increases the duty on coal-tar intermediates from 50 per cent ad valorem and 7 cents per pound based upon foreign valuation to 75 per cent ad valorem and 10½ cents per pound based upon American valuation. It increases the duty on coal-tar chemicals and dyes from 60 per cent ad valorem and 7 cents per pound on foreign valuation to 90 per cent ad valorem and 10½ cents per pound on American valuation. The increase amounts to more than 100 per cent, due to the change in figures and in the basis of valuation. It is provided that whenever there is no competitive American article affording a means of computing the American valuation, the ad valorem rate shall be based upon the foreign value or the export value, whichever is the higher. A proviso was included that in the exercise of the powers to change rates given to the President in the elastic tariff sections of the bill, no increase in rates may be made on coal-tar products.

Senators Moses and Smoot vigorously opposed the Bursum amendment, which was advocated by its sponsor and by Senators Wadsworth, Sterling, Lodge, Ransdell and Jones. Debate at times waxed warm, especially during the consideration in committee of the whole.

Senator Wadswoth introduced a letter written by Secretary of War Weeks, urging protection of the chemical industry of the United States as a matter of national defense. The letter, addressed to Senator McCumber, chairman of the Finance Committee, advocated extension of the embargo, but was read to the Senate in connection with the fight for higher rates.

Senator Moses of New Hampshire had previously demanded a separate vote on these rates before their final adoption, but when the matter was presented he declared that in view of the very decisive vote he would offer no further objection to their retention. His withdrawal from the fight against the dye provisions in such manner was the cause of much speculation and apparent discomfiture on the part of the proponents of the embargo provisions.

Embargo Abandoned

With the high rates of duty written into the bill it became apparent from the start that all chances of the embargo being adopted were eliminated. The rates were denounced on the floor of the Senate by varions Senators, but it was evident that the change of front was due to the knowledge that the flexible tariff provisions of this same measure will operate to lower excessive levies on many coal-tar products.

Senators Sterling and Lodge both contended that the increases were necessary to protect the American chemical industry from the standpoint of national defense. They asserted that under the elastic tariff provisions of the bill, the President undoubtedly would find it necessary and advisable to increase the rates on coal-tar products, but that an investigation by the Tariff Commission, necessary to present the facts to the President, would consume 8 or 10 months, then 60 days would have to elapse before a proclamation increasing duties could become effective and that in the meanwhile there would be a flood of German imports which would put the American industry out of business.

Acetaldehyde and Related Products

Several important changes in the chemical schedule of the tariff bill were made before the measure was passed by the Senate and sent to conference. After having first accepted an amendment by Senator France reducing the duty on acetaldehyde and allied chemicals from 6 cents per pound and 30 per cent ad valorem, to 20 per cent ad valorem, the Senate on motion of Chairman McCumber of the Finance Committee two days later reversed itself and restored the higher rate. Senator France, in securing adoption of his amendment, stated that these chemicals are not produced in the United States. In securing reversal of the action, Senator McCumber declared that there is production of these chemicals. Acetaldehyde and its related products—aldol, aldehyde ammonia, butyraldehyde, crotonaldehyde and paracetaldehyde—are finding an increasing use as intermediates, in manufacturing pig-

Chemical Foundation Defended in Senate

Senators Underwood and Wadsworth Express Support in Dye Tariff Discussion

As a result of the publicity which has been given to the Chemical Foundation matter and the speeches made in the Senate by Messrs. Underwood and Wadsworth, it is believed that the public has been convinced that there are two sides to the case. The fact that the Foundation has been defended by outstanding Senators of each party has had the effect of indicating that the defense is not being made for partisan political reasons.

Senator Wadsworth brought his defense of Francis P. Garvan, president of the Foundation, into his spirited support of the Bursum amendment to the dye schedule. He declared that if ever there was a deliberate attempt to break down and weaken the power of American self-defense, it has been made in connection with the American organic chemical industry. Senator Wadsworth's words were, in part, as follows:

> From what I have been able to learn of the history of organic chemistry in this country, especially in the dye industry, prior to our entrance into the World War, during our participation in the war and since the war, I am convinced that long before the United States actually declared a state of war the German Government and the cartel were in effect, although slyly, waging war against the peace and the safety of the people of the United States. We did not wake up to that situation until we ourselves got into the fight. The letter of the Secretary of War points out very briefly—all too briefly, according to my view—but sufficiently for the purposes of this discussion the predicament in which this republic of ours found itself when we were called upon to engage in our own defense.
>
> We went into the war and we learned the lesson at the cost of billions of dollars and many thousands of lives. We participated in the great victory and at the conclusion of the contest we asked for no territory; we asked no reparations; we asked for nothing of value to be taken from the vanquished, and we received nothing.
>
> We have the opportunity, as the result of the contest, an opportunity seized upon legally to maintain our public health with our own resources and without depending upon any foreign government or any foreign cartel, corporation or trust. We have secured the opportunity—and have secured it legally and properly as a result of our sacrifice and our efforts in the war—to maintain our national defense without depending upon any other nation, government, trust or cartel of any kind whatsoever. That is the prospect which confronts the American people today.
>
> It does not do, Mr. President, in discussing this matter, to drag the names of American citizens into the discussion and accuse them of dishonest motives because, forsooth, they take an interest in the perpetuation of this chemical industry here in America. It does not do, Mr. President, to bring inferences and insinuations against Francis P. Garvan; not by any means. I care not what his politics are; I understand he is a Democrat; I have known him since 1895 and known him well. He is an honest man, and he has no thought in his mind or motive in his heart except the safety of this country.
>
> I shall not discuss upon this occasion the wisdom or the unwisdom of the policy adopted by the last administration in the handling of the patents covering the dyes through the Chemical Foundation as trustee; that is not a part of this discussion; but I know full well, if I know anything about the psychology of this situation, that the attack upon the Chemical Foundation had a most material influence upon the votes cast on the question of the tariff on dyestuffs. It is for that reason that I deplored it at the time, although not publicly, for I had no opportunity to do so, but I deplore it now. It is not the question at issue.
>
> This organic chemical industry lies at the bottom of nearly everything we use. I firmly believe that the progress of the race from now on will be measured more by the progress in organic chemistry than in any other human effort. I believe that in organic chemistry lies the solution of the secrets of the past and of the future. I believe that its establishment and maintenance in this country, even under an embargo, mean the happiness, the progress, and the security of 100,000,000 people.
>
> I want to see the chemical laboratories of this country multiplied again and again. They cannot be multiplied, they cannot be maintained, no student will attempt to attend their courses, unless there is a chemical industry in which those students upon graduation may find a career.
>
> The two things—research in the laboratory and the successful conduct of a chemical industry—go hand in hand. Neither can proceed without the other.

The New York Senator concluded by expressing regret at the defeat of the embargo and a plea for the passage of the Bursum amendment.

Steel Treaters Announce Detroit Convention Plans

A preliminary program has been issued for the joint meeting of the American Society for Steel Treating and the American Drop Forging Institute, Oct. 2 to 7. The exposition of equipment will be held in the General Motors Building, and is open each day from 10 a.m. to 10 p.m. Technical sessions will be held in adjoining rooms, as follows:

Monday, Oct. 2, 2:00 p.m., general business meeting of the society.

Tuesday, Oct. 3, 10 a.m., Carburizing; 4 p.m., Metallurgical Education; 9:30 p.m., smoker.

Wednesday, Oct. 4, 10 a.m., General Heat-Treating; 2 p.m., Drop Forging; 4 p.m., Round Table on Practical Hardening; 9 p.m., carnival, frolic and dance.

Thursday, Oct. 5, 10 a.m., Tool Steels; 2 p.m., Alloy Steels; 4 p.m., Round Table on Practical Hardening; 7 p.m., banquet at Hotel Statler.

Friday, Oct. 6, 10 a.m., Non-Ferrous Session; 2 p.m., research.

A number of Detroit manufacturing establishments have extended an invitation to inspect their operations. Parties will be formed, and leave the General Motors Building daily at 10 a.m. and 2 p.m. During the week the committee on hardness testing of the National Research Council will also hold a symposium on hardness testing.

Accuse Janitor of Platinum Theft From Bureau of Standards

Responsibility for recent thefts of platinum from the laboratories of the Bureau of Standards is thought to have been fixed by the arrest of a negro janitor. Most of the stolen platinum was recovered from a Washington jeweler, to whom the janitor is said by the police to have sold the platinum in the very small amounts which he is said to have taken from time to time.

Rapid Strides in German Industrial Standardization

American Engineer Reports Inten Interest and Hearty Support of Standardization

"The day may not be far dista when American manufacturers w receive inquiries from oversea cou tries to furnish goods according to t German national standards, and behooves us to plan in time to me such conditions."

This statement is contained in a co munication to the American Engine ing Standards Committee from Osc R. Wikander, an American engine who has just returned from Germa where he represented that commit in conferences concerning the int national standardization of ball bearin

Describing the great strides standardization that have been made German industries. Mr. Wikander sa

"There is no doubt in my mind t one of the main reasons why forwa looking Germans force their standa ization work is because they want introduce German standards in great importing countries, and p sibly in the whole world. Holla Switzerland, Austria, Sweden many other European countries foll the German lead very closely.

"It was only a few years ago t the Normenausschuss der Deutsc Industrie, an organization corresp ing to our American Engineeri Standards Committee, was formed, the amount of work which it has ready accomplished is stupendous. Normenausschuss has already iss several hundred sheets of appro standards, and about twice as many already published as proposed sta ards. This enormous output of German organization has led many believe that it was merely a fact producing 'paper standards' and that work was not to be taken very serious A personal investigation convinced that this is not the case, and I fo that the great output of standards merely due to the enormous efforts forth and to the enthusiasm of great majority of the interested part

"This enthusiasm is due to a m or less general recognition, crea under the pressure of war conditi of the great economic value of standa ization and to the very generally cepted opinion that a standardi industry would be one of the strong weapons in Germany's struggle economic rehabilitation."

Centrifugal Casting Equipme Installed at Pipe Works

The United States Cast Iron Pip Foundry Company has recently eq ped its North Birmingham plant four machines to be used in the ma facture of cast iron pipe by de Lavaud centrifugal method.

It is stated that this type of pipe can be made much lighter t pipe made by the old method and at same time will stand greater press

Denies Fraud in Sale of Nashville Powder Plant

Purchasers of Old Hickory Smokeless Plant Plead Not Guilty of Conspiracy to Defraud Government

Ernest C. Morse, former director of ...es of the War Department and now ...sident of the Foreign Sales Supply ... of New York, pleaded not guilty ... the District of Columbia Supreme ...urt to the indictment charging con...racy to defraud the government in ...nection with the sale of the Old ...ckory plant at Jacksonville, Tenn.

Over the protest of government ...nsel the court granted the defend...t until Sept. 20 to file a motion to ...ash the indictments. He furnished ...000 bail on each of the two charges.

Everly M. Davis, president of the ... M. Davis Chemical Co., and Alexan...r W. Phillips, associated with Davis, ...th of New York, who were indicted ... the Old Hickory case with Morse, ...re also arraigned and pleaded not ...ilty.

Attorney Mayer, who accompanied ...rse to Washington, later made the ...llowing statement:

"Mr. Morse appeared today in the ...ited States Court and pleaded not ...ilty to the indictments found against ...m. At the time of the investigation ... the Graham committee, Mr. Morse ...peared voluntarily, waived all im...nity and under oath answered all ...estions of the members of the com...ttee.

"It is regrettable and surprising that ...r. Morse, who occupied the position ... director of sales of the War Depart...ent and who, under instructions of ...e Secretary of War, directed the sale ... more than two and one-half billions ... dollars' worth of government prop...ty, should not have been called before ...y other government agency or official ...vestigating the sale of war surplus.

"The indictments having been found ...der such circumstances, Mr. Morse ... obliged to wait until the trial of the ...dictments, to place before the public ...cts which will completely vindicate ...m of the charges made."

Open-Hearth Patent Complications Relieved

All patents and patent applications ...lating to combustion in regenerative ...rnaces, known as the McKune, Dan...rth and Engler systems, have been as...gned to the Union Trust Co., of Cleve...nd, by the Miami Metals Co., Blair ...ngineering Co., and Arthur G. McKee ... Co. Acting as trustee, the Union ...rust Co. has appointed the Blaw...nox Co. of Pittsburgh agent for ...e exclusive sale and manufacture of ... equipment by these patents. This ...nsolidation will assure to the steel ...dustry the best that has been devel...ed under all of the above mentioned ...sic patents, combined in one design, ...d will also remove the possibility of ...y patent interference in the use and ...eration of these equipments.

American Engineers Represented at Rio de Janeiro Exposition

The appointment of Calvin W. Rice, secretary of the American Society of Mechanical Engineers, as official delegate to the Engineering Congress to be held in connection with the International Exposition at Rio de Janeiro is announced at the national headquarters of the society in New York City. Mr. Rice, who goes as the emissary of organized engineering in the United States, and who for purposes of representation at the Congress has been elected an honorary vice-president of the society, will sail from New York Aug. 23 on the steamship Pan-America, which will convey Secretary of State Charles E. Hughes and his party to the Brazilian capital.

Mr. Rice's journey was called by officials of the society the opening of a new chapter in international relations among engineers. For many years, it was stated, this society has been active in laying the groundwork of a close union of thought and effort among the engineers of the world as a part of an elaborate plan of public service which is being gradually linked to the technical activity of the organization. In addition to the American Society of Mechanical Engineers, Mr. Rice will represent at the Congress the Federated American Engineering Societies, the American Institute of Electrical Engineers, the Engineering Foundation, the John Fritz Medal Board, the Engineering Division of the National Research Council, the Engineers' Club of New York City and other organizations.

A dinner in honor of Mr. Rice was given at the Engineers' Club, New York City, Aug. 21. Distinguished engineers, publicists and educators from many cities were present. John W. Lieb, vice-president of the New York Edison Co., acted as the toastmaster. The committee of arrangements included Charles F. Rand, chairman of the Engineering Foundation; W. F. M. Goss, president of the Railway Car Manufacturers' Association, and Roy V. Wright, of the Simmons-Boardman Publishing Co.

Chemical Warfare Gas Used as Fumigant

The work of the Chemical Warfare Service on the use of cyanogen chloride as a fumigant for ships and on the use of toxic materials in anti-fouling paints was described in these pages July 5, 1922. It was stated that this work was done in co-operation with the navy's marine biological laboratory at Beaufort, S. C. This statement was in error, as the laboratory is located in Beaufort, N. C.

The work in question was under the direction of Captain H. Williams of the Bureau of Construction and Repair, Navy Department, Washington, D. C. Captain Williams is a specialist on the use of toxic materials in anti-fouling paints.

Predicts Growth of Chemical Export Trade

C. R. DeLong, Chief of New Chemical Commodity Division, Optimistic on Prospects for Development

Expressions from American consuls in many countries as well as from other agents of the Department of Commerce, coupled with conclusions being reached in the course of economic studies being made at Washington, lead C. R. De Long, chief of the Chemical Commodity Division, to predict a gradual expansion of the chemical export trade. He expects American manufacturers to hold many of the markets supplied by them during the war and expects to see them compete successfully with the Germans in many fields. He does not believe that German competition in Latin America and in some other countries is as formidable as many think.

As internal readjustment in Germany catches up with the depreciated mark, German manufacturers will have to advance their prices, but judging from the reports on file in Mr. De Long's office, purchasers of chemicals in many countries have had unfortunate experiences with materials of poor quality and are more ready than ever to listen to quality arguments. Mr. DeLong thinks the danger from retaliatory duties, likely to grow out of the passage of the pending tariff bill, have been over-played. Since practically all countries have been forced to increase their tariffs recently, there is a much more general realization of the need for such action.

Plans of New Division

One of the first steps Mr. DeLong will take in the effort to make his division serviceable in the development of the export trade will be to obtain the appointment of advisory committees with whom he can keep in close contact. He will ask each individual trade concerned with exports to designate such a committee. At the present time, the lists of firms engaged in the exportation of chemical commodities are being revised carefully so that advance notices of probable needs abroad may be sent to them.

Plans now are being formulated for a statistical service covering those commodities where the need is apparent. The great mass of reports which reach the department daily from all parts of the world will be carefully scanned for current information which has a bearing on the demand for chemicals. In addition special economic studies of purely chemical interest will be undertaken from time to time. In some cases this will cover the world situation as it pertains to some chemical commodity and in others the possibilities of extending the market for American chemicals in a single country will be studied.

A number of important industrial groups have already offered their co-operation in this work and Mr. DeLong is hopeful that the industry will stand squarely behind the new division.

Electrochemical Society Meeting Promises Well

Symposiums on Electrodeposition and Industrial Heating Features of Technical Sessions

Final arrangements for the forty-second general meeting of the American Electrochemical Society, at Montreal, Que., are being made and indications are that the meeting will be a success.

The meeting will be opened by President Schluederberg on Thursday morning, Sept. 21. The technical program will include the presentation and discussion of papers on electrolysis and electroplating. The recently organized division on electrodeposition, of which G. B. Hogaboom is chairman, will be well represented and take active part in the discussion of these papers. One of the papers of the Thursday morning session will deal with the physical properties of electrolytic iron—a product which is being turned out commercially, contrary to all predictions of 10 years ago. There will also be papers on zinc, brass and other metals.

Industrial Heating Symposium

On Thursday afternoon and Friday morning a very interesting symposium on "Industrial Heating" will be in progress. The electrothermic division, of which Bradley Stoughton is chairman, held a most successful symposium on "Electric Cast Iron" at the Baltimore meeting last April, and will be in charge of this discussion. Twelve papers especially prepared for this session and dwelling on industrial heating in electric furnaces, other than fusion and melting furnaces, will be open for discussion. There will be papers on the following subjects: "History of Industrial Heating," "Principles of Design of Furnaces," "Comparison of Fuel Costs in Different Types of Electric Furnaces, and With Combustion Furnaces," "Resistor Materials," "Specific Heats," "Electric Conductivity of Insulating Materials at Industrial Furnace Temperatures," and "Heat Transfer."

An excursion to Shawinigan Falls has been arranged, affording members a rare opportunity to inspect the various industrial plants of one of the most progressive centers on the continent.

A popular lecture on the "Progress in Physical Science" is scheduled for Thursday evening. Section Q will be in charge of an old-fashioned smoker on Friday evening.

Headquarters for the meeting will be the Hotel Windsor.

Hoover Denies Report of Metric System Indorsement

Wide publicity has been given a news article to the effect that Secretary of Commerce Hoover has indorsed the metric system. Mr. Hoover states that he is at a loss to understand how such a report originated. He has not indorsed the compulsory use of the metric system, he says.

Manufacturing Chemists' Association Meets

The regular monthly meeting of the Manufacturing Chemists' Association was held in New York, Aug. 16. The association's committee on standardization announced that its report is in preparation and will be printed within a few weeks. The practicability of glass-lined steel carboys for acid shipment was discussed and referred to a committee for further consideration.

Free Port Provision Part of Tariff Bill

Establishment of Free Entry Ports for Reshipping Seems Assured by Senate Support

Establishment of foreign trade zones at a number of American ports practically is assured by the action of the Senate on Aug. 16 in adopting, with practically no opposition, an amendment to the tariff bill which would authorize the creation of such zones. The plan for the so-called free port has been denounced by ultra-protectionists as a free-trade scheme. To meet some of the objections voiced against the proposal, the Senate committee eliminated from the original amendment the authority to establish manufacturing enterprises within the free zone. It will be possible, however, to store, exhibit, break up, repack, assemble, distribute, sort, refine, grade, clean, mix and otherwise manipulate foreign or domestic merchandise in an area where no compliance with the laws and regulations governing the entry of merchandise will be required.

Vexations of Custom House

Under existing law any goods landed in this country must pass through the Custom House. If they are re-exported 99 per cent of the duty paid is refunded. In addition to the loss of 1 per cent of the duty, there is the more important consideration of vexatious and costly delays in complying with the red tape which accompanies entry through the Custom House and the subsequent dispatch of the foreign goods after they have been mixed with domestic merchandise or assembled in different forms.

Should Aid Shipping

The delays and annoyances of this procedure were such as to discourage almost entirely any handling of foreign merchandise in transit. By making this possible it is believed that substantial advantages will ensue to American industry and to American shipping. Many ships come to the United States in ballast it is declared which would bring cargoes for transshipment to various other countries were it not for the difficulties of our customs regulations. One of the great advantages of allowing transit privileges on foreign cargoes is the fact that on their re-assembly at American ports domestic merchandise will be mixed with the shipments of foreign origin.

Demand Action on Water Pollution Bill

Permanent Organization Formed to Push Representative Appleby's Bill Through Congress

Officials of Atlantic seaboard cities and others interested in ending the pollution of navigable waters by oil have formed a permanent organization to be known as the National Coast Anti-Pollution League. The new body elected as president Gifford Pinchot, Republican nominee for Governor of Pennsylvania, and adopted a resolution calling upon Congress to pass the bill of Congressman T. Frank Appleby of New Jersey making it a federal offense, punishable with a fine of $2,500, to dump oil on navigable waters.

Will Support Appleby Bill

At a meeting of representatives from various resorts and cities on the Atlantic coast held in Atlantic City last week this action was taken. Meetings were held on Aug. 10 and 11, at which prominent speakers emphasized the damage done by oil pollution. The feeling was unanimous that steps should be immediately taken to abate the menace. Representative Appleby said that in 1919 the total tonnage of American oil-burning vessels was 5,000,000, but that in 2 years it has increased to 19,000,000. Oil pollution has increased correspondingly, he said.

Considerable discussion centered around the question of whether the resolution should be worded to support Congressman Appleby's measure specifically. It was finally decided to pass a resolution demanding passage of the Appleby measure at the incoming session of Congress. Copies of the resolution will be forwarded to members of Congress.

Government to Consider Means

A meeting of representatives from the departments of the government concerned in the water pollution problem will shortly be held at the Department of State.

These delegates will consider the general issues involved in connection with the calling of an international conference of maritime nations, in pursuance of the joint resolution of Congress, approved July 1, 1922, with a view to the adoption of effective means for the prevention of the pollution of navigable waters by oil-burning and oil-carrying steamers.

The Department of State will be represented by Stanley K. Hornbeck; the War Department by Lieutenant-Colonel G. B. Pillsbury, Engineers Corps of the army; the Navy Department by Captain H. E. Lackey; the Interior Department by R. Van A. Mills, Bureau of Mines; the Department of Agriculture by George A. Lawyer, Chief Game Warden; the Department of Commerce by Henry O'Malley, Commissioner of Fisheries, and the Shipping Board by W. E. Griffith.

Tariff Bill Boosts Chemical Items

(Continued from page 371)

ments, in the production of synthetic resins and as accelerators in rubber vulcanizing. Aldol has promising future use in the flotation process of ore concentration, particularly copper ore.

A similar fate was suffered by an amendment to the rate on sodium nitrite, except that in this case the amendment increased the duty while the Senate subsequently reduced it. Senator Jones of Washington secured adoption of an amendment increasing the nitrite rate from 3 to 5 cents per pound, the Senate on motion of Senator Robinson reversing this decision the following day and restoring the duty of 3 cents, which was the rate as the bill came from the House.

Camphor Rates

Through an amendment offered by Senator McCormick and indorsed by Senator Smoot, the duty on camphor will be increased to 25 per cent ad valorem whenever it is made to appear to the satisfaction of the President that manufacturers in the United States are producing 2,000,000 lb. of synthetic camphor a year. The rates carried in the bill are 1 cent a lb. on crude camphor and 6 cents per lb. on refined or synthetic camphor. These specific duties are materially lower than an ad valorem duty of 25 per cent would be. The object of the amendment is to encourage the production of synthetic camphor in this country as a club over the Japanese control of the natural camphor market. During the war the Monsanto Chemical Co. of St. Louis spent about $500,000 in a plant for the manufacture of synthetic camphor, according to Senator Smoot, but this is threatened now by the Japanese competition. Whenever the total output of synthetic camphor in the United States reaches 2,000,000 lb. a year, the higher duty will go into effect to protect the industry.

Arsenic on Free List

While the bill was under consideration in the Senate, Southern Senators were successful in having arsenious acid or white arsenic stricken from the dutiable list and placed on the free list. This product is being used extensively in fighting the boll weevil and other pests of agriculture. The House imposed a rate of 8 cents per pound, the Senate Finance Committee reducing this to 2 cents and this final action makes it duty free.

Magnesium Compounds

Rates on several magnesium products were reduced by the committee. As adopted by the Senate they are: carbonate, precipiated, 1½ cents per pound; chloride, anhydrous, 1 cent per pound; chloride, not specially provided for, one-half cent per pound; sulphate or epsom salts, one-half cent per pound; oxide or calcined magnesia, medicinal, 3½ cents per pound; oxide or calcined magnesia not suitable for medicinal use, 3½ cents per pound, this last being an increase over the original rate.

Barytes

Barytes rates were reduced by the Finance Committee to the figures of the House Ways and Means Committee, which are $4 per ton on the crude ore; $7.50 per ton if ground, and 1 cent per pound on precipiated barium sulphate or blanc fixe.

Chalk

The Finance Committee increased from 20 to 30 per cent the duty on chalk or whiting or paris white, if dry, ground, bolted or precipitated. The original recommendation of the committee was for a 35 per cent duty, but this was reduced to 20 per cent when the paragraph was adopted in May, being raised to 30 per cent in the last week of Senate consideration of the bill.

Vegetable Extracts

On recommendation of the Finance Committee, the duty on vegetable extracts for dyeing and tanning—chestnut, cutch, chlorophyll, divi-divi, fustic, hemlock, logwood, mangrove, myrobalan, oak, Persian berry, quebracho, sumac, saffron, safflower, saffron cake, valonia, wattle and others not specially provided for—was reduced from 25 to 15 per cent.

Potassium Compounds

The Finance Committee increased from 1 cent to 2 cents per pound the rate on potassium chlorate and perchlorate. In the potassium paragraph of the bill the committee also struck out the proviso which imposed 15 per cent duty ad valorem duty for 5 years, in addition to the specific rates, the effect being to reduce all rates on potassium products.

Metals Schedule

As passed by the Senate, the Fordney-McCumber tariff bill provides rates in the metals schedule generally lower than those fixed in the measure as it was adopted by the House. This difference was true as the bill was reported by the Senate Finance Committee, and during the weeks of consideration the changes in metals from the committee's original figures have been downward with only a few exceptions.

In the last week of Senate consideration of the bill the Finance Committee reduced the rate on high-speed steel 7 per cent by cutting the duty on steel valued at more than 16 cents per pound to 20 per cent ad valorem, from the original figure of 25 per cent, and decreasing from 10 to 8 per cent the additional duty paid on steel containing more than six-tenths of 1 per cent of metallic alloy.

Metallic Magnesium

Rates on metallic magnesium were reduced in the final days of Senate debate on the bill on motion of Senator Phipps of Colorado, which was not resisted by the Finance Committee. As rewritten, the rate on magnesium in the crude, ingots, alloys or scrap stands in the bill at 10 cents per pound instead of 50 and 40 cents, as provided in the different classifications as originally drawn; the rate on the metal in coils, plates, sheets and other unfinished forms is 20 cents per pound instead of 40 cents, while the rate on ribbons, tubing, powder and other finished articles remains at 40 cents per pound upon the metallic magnesium content and 20 per cent ad valorem.

Aluminum

Repeated efforts were made at various stages of the bill in the Senate to reduce the duty on aluminum from the figures of 5 cents per pound on the crude and 9 cents per pound on the prepared, which were fixed by the House and unchanged by the Finance Committee, but all of these were unsuccessful. Vigorous attacks upon the Aluminum Company of America were made by the Democratic side and Senator Reed of Missouri insinuated that the influence of Secretary of the Treasury Mellon, listed as a director of this corporation, had been felt in fixing these rates. The latter charge brought a heated rejoinder from Senator McCumber, who denied that any person connected with the Treasury Department had had any connection with determining these rates and pointed out that in the first nine months of 1921 imports of unmanufactured aluminum were more than 24,000,000 lb., while exports were barely more than 1,000,000 lb.

Nickel

The Senate committee reduced from 5 to 3 cents per pound the rate on nickel. No change was made in the House rate of 1½ cents per pound on lead-bearing ore. The House rates on zinc ore, which provide a sliding scale according to the zinc content, also were unchanged, but rates on manufactures of zinc were increased slightly. The basic copper rate of 2½ cents per pound in rolls, rods or sheets was not changed.

Pig Iron

The duty on pig iron, kentledge and spiegeleisen was reduced from $1.25 per ton to 75 cents per ton during the last week of Senate consideration of the bill and scrap iron and scrap steel was reduced from $1 to 75 cents per ton.

The rates on all alloys were reduced below the figures fixed by the House Ways and Means Committee, and in its final summing up of the bill the Senate made no changes from the figures which were fixed upon these alloys in May and June.

Most of the reductions made in the metals schedule came in the manufactured articles. In the last week of consideration, the Finance Committee increased by 5 per cent the duties on woven-wire cloth of any metal, but while the figures are five points above those fixed in the House bill, the rates actually are lower as the measure stands now because of the difference in the valuation basis used by the two houses of Congress.

Treasury Department Ruling Will Stop Import of Canadian Iron Oxide

Acting under the authority of the anti-dumping clause of the emergency tariff law of May 27, 1921, which forbids the dumping of imported merchandise into the United States at prices less than the product is sold for in the country of origin, the Treasury Department has issued an order forbidding the dumping of oxide of iron. In an order published by the Treasury Department, Assistant Secretary Clifford announces that after investigation it has been found that the oxide of iron manufacturing industry in the United States is being, or is likely to be, injured by reason of the importation into the United States of oxide of iron from the Province of Quebec, and that such merchandise is sold, or is likely to be sold in the United States at less than its fair value.

The effect of this announcement is to forbid the importation of oxide of iron from the Province of Quebec, unless American purchasers arrange to pay the price which is charged for the product in Canada. Section 201 of the emergency tariff law provides that if the Secretary of the Treasury finds that articles are sold in this country cheaper than in the country of origin, the importation of the merchandise is prohibited.

Tariff Bill Prohibits Import of U. S. Trademarked Goods

In the closing days of the Senate debate on the tariff bill, the Finance Committee introduced an amendment which was adopted and incorporated in the administrative sections of the measure, making it unlawful to import into the United States any merchandise of foreign manufacture which bears a trademark registered in the Patent Office by a person residing in this country.

This provision is of especial importance to the chemical industry as its application is particularly directed to trademarks on products of patents seized by the Alien Property Custodian during the war and sold to American corporations through the Federal Trade Commission or the Chemical Foundation.

As the tariff bill was reported to the Senate by the Finance Committee, practically the same provision was contained in the paragraph on coal-tar chemicals and dyes. It was stricken out of this paragraph several days before the item was taken up in debate because of objections entered by Senator Moses of New Hampshire. Nothing more was heard of the provision until the last day fixed for consideration of Finance Committee amendments, when it was re-introduced by the committee as a section of the administrative title of the bill. Senator Moses opposed it on a point of order, debate being cut off by the time the section was reached, but he was overruled and the section was adopted.

Du Pont Dye Royalties Amounted to $72,000

Answer to Foundation Suits Announces Payments Made to Treasury During License Period

Answer has been filed by E. I. du Pont de Nemours & Co. to the two suits brought against it and the Treasurer of the United States by the Chemical Foundation for an accounting of royalties paid for the use of German dye patents. The suits involve the money paid for the use of these patents from April 10, 1919, when they were purchased by the Foundation, to Sept. 1, 1920, on which date the government license, under which the operations had been conducted by the du Pont company, was terminated.

The action is based on the Chemical Foundation's contention that all moneys paid under license for the use of the German patents from the day they were purchased should go to the Foundation and not to the United States Treasury.

The du Pont company is party to the suit only because it has already paid the money into the United States Treasury, and the action seeks mainly to discover the amount so paid. In each case the answer recites that the company obtained its license from the Federal Trade Commission, and operated under this license until the date of its termination in September, 1920. It sets forth in each case the amount of money, $61,884.98 and $10,103.88, which was paid to the Alien Property Custodian from April 1, 1919, to September, 1920. The answer also says the amount paid was a fair and reasonable royalty for all use made of the inventions.

Employment Service Offered by Four Engineering Societies

Attention is called to an employment service for engineers of every variety of training and experience which is conducted by the four national engineering societies of the United States. This service brings in touch with the various business men the service of 50,000 trained technical men who are members of these societies and one of the objects of it is to show to the various commercial houses the aid which engineers are rendering to others in the same lines and to help these firms and corporations secure similar assistance. Men of engineering training are prominent in all branches of commercial endeavor and their creative ability is recognized as being of great help in the building up of the nation's wealth.

This service is in a position to supply chemical engineers, civil engineers, mechanical engineers, electrical engineers, sales engineers, production managers, superintendents and other trained executives. It is under the direction of W. V. Brown and is located in the United Engineering Building, 29 West 39th St., New York City. Service is free to both employer and to employee.

Refractory Companies Merge

The General Refractories Co., Pittsburgh, Pa., has arranged for a bond issue of $4,000,000, the proceeds to be used in part for perfecting a merger of different refractory interests. The company will take over the General Refractories Co. of West Virginia, as well as the Standard Refractories Co., Clayburg, Pa., the latter acquisition involving $1,500,000. The Claysburg works will be operated in conjunction with the company's plant at Sproul, Pa., in this same section. The company will operate, in all, twelve plants in Pennsylvania, Kentucky and Illinois, with annual output of 247,000,000 bricks and shapes. William C. Sproul is president of the company.

Personal

J. Thompson Brown has been appointed general manager of the explosives department of E. I. du Pont de Nemours & Co., Wilmington, Del., succeeding the late Charles A. Patterson.

R. H. B. Elkins, formerly manager of the New York office of the Duriron Co., Inc., of Dayton, Ohio, has been promoted to the newly created position of chemical engineer for the same firm. Mr. Elkins will make his headquarters at the New York office and will devote his entire attention to the solution of problems for the company's customers.

Prof. Grinnell Jones, of the chemistry department of Harvard University, has been called to Washington, where his services are to be required during the months of August and September by the United States Tariff Commission.

Dr. Victor K. LaMer has been appointed Cutting Traveling Fellow by Columbia University and will sail on Sept. 13 for a year's study and travel in England and on the Continent. He will investigate especially the subjects of food and physical chemistry.

George A. Prochazka, of the Central Dyestuff & Color Co., is in Europe with his family on a vacation trip.

Howard Rhode, of the Lehigh Portland Cement Co., Allentown, Pa., gave an interesting address on the "Manufacture and Marketing of Cement," before the members of the Square Club, on Aug. 8.

Obituary

William G. Price, head of William G. Price & Sons, Chester, Pa., leather manufacturers, died at his home, in Philadelphia, Aug. 7, aged 58 years. He was a member of the Manufacturers' Club and the Philadelphia Country Club, and widely known in the leather industry. He is survived by his wife, two sons and a daughter.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Dyes and Other Synthetic Organic Chemicals

A Brief Summary of Some of the Principal Features in the United States Tariff Commission's Recent Census of Production, Imports and Exports During 1921

AS WAS indicated in its preliminary report[1], the United States Tariff Commission's "Census of Dyes and Other Synthetic Organic Chemicals, 1921," shows an appalling decrease in production. Our output of finished dyes, 39,008,690 lb., was only 46 per cent of the 1920 production. Intermediates fell off 73 per cent in quantity. On the other hand, the total importations of coal-tar dyes during 1921 was in considerable excess of the 1920 receipts. Reducing the vat dyes to a single-strength basis, the total quantity of dyes imported in 1921 was 4,252,911 lb. and the value was $5,156,779.

Exports of domestic dyes for 1921 showed a decrease of 79 per cent as compared with the previous year. The combined value of exports of "aniline dyes" and "all other dyes" for 1921 was $6,270,155, while in 1920 it was $29,823,591 and in 1919, $15,728,499. Very significantly the commission states "this great reduction in our export trade may be attributed in part to the general business depression, but the chief cause was the appearance in the principal foreign markets, such as China, India, and Japan, of German dyes, with which the domestic producers have been unable to compete."

The Tariff Commission's census this year includes, for the first time, production statistics for all synthetic organic chemicals, whether derived from coal-tar, non-coal-tar or natural sources. Included among these are the acids, alcohols, esters, ketones, aldehydes, alkaloidal derivatives, carbocyclic compounds, etc., such as are used as perfume and flavoring ingredients, solvents, medicinals and in numerous industrial processes. The output of these materials in 1921 was 21,545,186 lb. and the sales amounted to 16,761,096 lb., valued at $13,746,235. Included in the production figure are 1,129 lb. of research chemicals, the sales of which totaled 428 lb., valued at over $18 per pound.

[1]See *Chem. & Met. Eng.*, vol. 27, No. 1, p. 31, July 5, 1922.

Dyes and Finished Products

The Tariff Commission accounts for the greatly reduced output of dyes in 1921 by (1) the loss of most of our export trade, (2) the large stocks carried over from the previous year and (3) the general business depression. In addition, reference might have been made to (*a*) the uncertainty regarding the tariff situation and (*b*) the continued inactivity of the principal textile mills resulting from the long-drawn-out labor difficulties.

The three dyes — sulphur black, indigo and agalma black 10B—accounted for 40.8 per cent of the total production of dyes in 1921. Sulphur black led with 7,832,696 lb. (20 per cent of total output); indigo was second with 6,673,968 lb. (17 per cent) and agalma black 10B followed with 1,426,194 lb. (3.7 per cent). The 1921 production when classified according to method of application on the fiber shows decreases for practically every class. Production and imports are compared graphically in Fig. 1. It will be noted that only in the case of vat dyes other

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	150.92
Last week	150.87
August, 1921	158
August, 1920	264
April, 1918 (high)	286
April, 1921 (low)	140

Prices for the twenty-five commodities included in this index were practically without change during the past week. Aniline oil was advanced from 14c. to 15c. per lb., but this had only a very minor effect on the index number.

FIG. 1.—PRODUCTION AND IMPORTS OF DYES COMPARED BY CLASSES.
IMPORTS 1914 FISCAL YEAR. PRODUCTION 1917—1921. CALENDAR YEARS
IMPORTS 1920 AND 1921 CALENDAR YEARS.

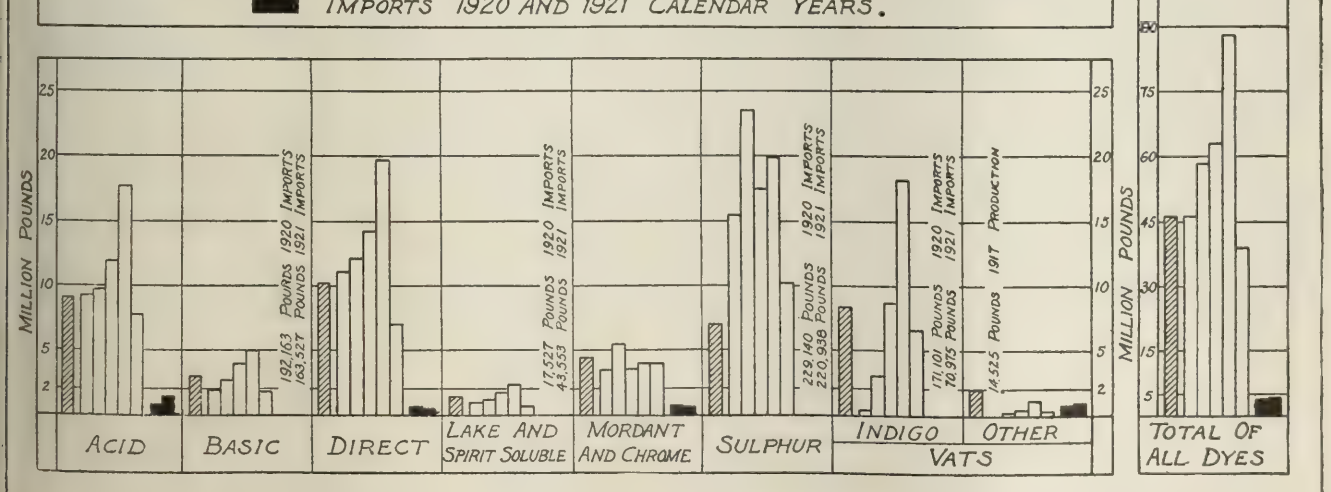

FIG. 2.—VALUE OF DOMESTIC DYES EXPORTED BY MONTHS.

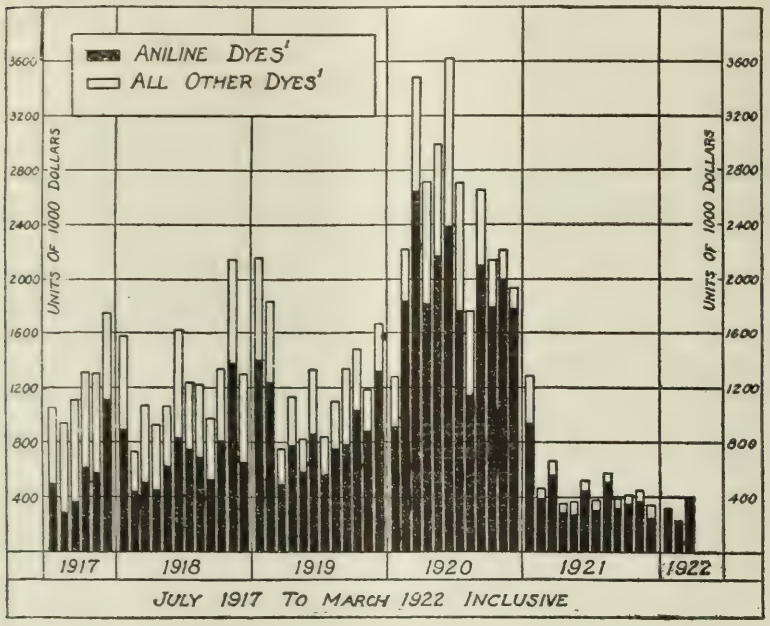

than indigo is the domestic production considerably less than the 1914 imports. In commenting on this situation the report adds:

> The progress of the year included the manufacture for the first time in this country of a considerable number of colors of greater complexity and more specialized application. The development of these products is a technical achievement, highly creditable to the industry. Many of these new products were among the more important colors not heretofore manufactured in the United States and the domestic production of these products is an important step toward a self-contained industry. This progress has continued in the spring of 1922 and production of new dyes has been reported in the first 6 months of the latter year. The domestic dye industry is still somewhat deficient, however, in the manufacture of vat dyes, alizarins and certain special types.

CRUDES AND INTERMEDIATES

In the brief space at our disposal for this presentation it is possible to comment on only a few of the many interesting details included in the commission's compilations. A significant feature in connection with the production of coal-tar crudes is that 78 per cent of the output of coke was from byproduct ovens in 1921, as compared with 60 per cent in 1920. This increase assures the dye industry of more than adequate supplies of its basis raw materials.

Intermediates were produced in 1921 by 108 different firms which reported an output of 70,899,912 lb. Of this quantity 33,637,326 lb. was sold for $8,483,463. Table I includes the more important intermediates used in making the dyes which represent the bulk of our consumption. The percentages in the last column show the decrease in the 1921 output from that of 1920.

TABLE I—PRODUCTION OF PR NC.PAL INTERMEDIATES

	Production in lb.	Per Cent of Decrease
Aniline oil	5,639,234	86
Benzidine	328,577	85
Gamma acid	218,717	48
H acid	1,639,323	68
Alpha-naphthylamine	429,055	92
Beta naphthol, tech	2,959,049	75
Para-nitroaniline	832,438	61
Anthraquinone	125,358	77

EXPORT TRADE IN DYES

Unfortunately the Commerce Department's classification of exports of domestic dyes does not give the detail that would make possible any accurate comparison with either production or imports. Their classification shows, by value only, (1) aniline dyes, (2) logwood extracts and (3) all other dyes and dyestuffs. For the first time quantity as well as value was published in 1921. The combined value of exports of aniline dyes and all other dyes for 1919 was $15,728,499 as compared with $29,823,591 for 1920. In 1921 this figure showed a sharp decline to $6,270,155. The greatest export of aniline dyes for any month of 1921 was in January, when $943,595 worth was shipped; the smallest monthly total was in December, amounting to $254,878.

OTHER USEFUL DATA

Among other valuable features of this report, which was prepared with the assistance of Warren N. Watson, Dexter North and Carl R. DeLong, are the following: Detailed tabulation of domestic production of individual crudes, intermediate and finished coal-tar products (dyes, color lakes, photographic chemicals, medicinals, perfumes and flavors, synthetic phenolic resins, and synthetic tanning materials); a census of dyes imported during 1921 with names of foreign manufacturers and countries of origin; a census of synthetic organic chemicals not of coal-tar origin (perfume chemicals, ethers, esters, medicinals, butyl alcohol and derivatives, and acetylene, ethylene and propylene derivatives.)

Two important and useful compilations are the names and addresses of 175 manufacturers of coal-tar products and 62 producers of synthetic organic chemicals.

The New York Market

NEW YORK, Aug. 21, 1922.

The acute fuel shortage and railroad difficulties were the subjects of most concern in the chemical market during the past week. There has already been a marked decrease noted in the manufacture of several important basic commodities. Producers of caustic soda and soda ash have been forced to buy coal at the present high prices and their costs of production have naturally advanced. The present situation as far as fuel is concerned is generally considered quite unfortunate, coming at the approach of the fall season, when manufacturers were preparing to open extensive campaigns for an increased volume of business.

GENERAL AND SPECIAL CHEMICALS

Barium Carbonate—Spot material held around $62@$63 per ton, with shipment figures at $61. Trading was mostly for small lot requirements.

Bicarbonate of Soda—Producers are holding the market quite steady at 1⅞c. per lb., in barrels, f.o.b. works. The demand is fair.

Bichromate of Potash—Several moderate-sized sales were recorded at 10½c. per lb. Factors were not desirous of breaking away from these figures. Increased producing costs have been the underlying reason for the advance and strength in this commodity.

Bichromate of Soda—Prominent factors maintained prices at 7⅜c. per lb. for round lots and 7½c. for fair-sized quantities. Some resale lots were recorded around 7¼c. per lb. The demand is quite active and has prevented any accumulation of spot stocks.

Caustic Soda—The market is in an exceedingly strong position, due to the pronounced coal shortage. Export demand at the new figures has been very difficult to meet, with only a few sales of standard brands reported sold at $3.65@$3.70 per 100 lb. Contract prices were advanced in some directions, while in others 2½c. per lb. basis 60 per cent, was being quoted for regular shipments.

Copper Sulphate—Most of the agricultural demand has been satisfied and the market is returning to a more normal situation. Spot supplies are scarce at 6½c. per lb. Producers quote 99 per cent large crystals at 6c. per lb., for prompt shipment.

Nitrite of Soda—Leading factors continue to quote 9c. per lb. f.o.b. works, but resale goods have been sold down to 8c. per lb.

Oxalic Acid—The advance in spot quotations has been firmly maintained. Sales at the works have been made as high as 16c. per lb., with spot goods generally heard around 16½@16¾c. per lb. The demand is quite lively for moderate sized quantities.

Prussiate of Soda—The market has not shown any signs of activity of late and trading was mostly for small quantities. The range is around 20½@21c. per lb.

The St. Louis Market

ST. LOUIS, MO., Aug. 17, 1922.

Conditions in the chemical market in this locality are very good, both as to general activity and favorable trend of prices. The movement during the past 2 weeks, particularly of heavy chemicals, has been quite extensive, and while a part of this increase may be attributed to the transportation situation, we believe that a greater part of it is due to the fundamental soundness of industrial conditions throughout the country, as the broadening has not been sudden, but steady from month to month since the beginning of this year.

ALKALIS

The market on alkalis continues in the same trend save for a few large orders placed in anticipation of a complete railroad tie-up. *Caustic soda*, solid, in 5- and 10-drum lots is being quoted at $3.90 and the flake at $4.25. This price has been shaded in several instances, but holds good with all reliable dealers. *Soda ash* is moving in normal volume and is being quoted at $2.20@$2.35 in 1- to 5-bag lots; on carload business as low as $1.85 per 100 lb. for 58 per cent light is being done. *Bicarbonate of soda* can be had at $2.35 in 5-bbl. lots, having advanced somewhat recently. Carload business is being done at around $1.85 per 100 lb., f.o.b. buyer's point. *Sal soda* is just now the weak member of the alkali group. Strange as it may seem, this item is affected by the miners' strike, and the wholesale grocers of St. Louis do a large volume of business throughout the mining district.

GENERAL AND SPECIAL CHEMICALS

Citric acid is very quiet, and this being the last of the season not much is to be expected in the way of heavy purchases, as consumers will buy only enough to tide them over. Stocks are plentiful and prices remain the same. Makers of *oxalic acid* are sold up, and it is very difficult to find spot goods. Quotations for immediate delivery are around 16¾c.@17c. per lb., f.o.b. producers' works, but for future delivery it is understood that this price could be shaded somewhat. Supplies of *white arsenic* are still very scarce and the market continues to be very strong, prices ranging from 7½c.@8c., f.o.b. New York. Stocks of *blue vitriol* in this market are nil, but as the demand for insecticides is practically at an end, there should be freer movement of this article in the next few weeks. *Carbon bisulphide, technical*, remains in heavy demand, but it is not expected that this will continue for any length of time, as the season for this product is about to come to a close. *Carbon tetrachloride* is moving in a routine way. *Copperas* is still very scarce, and when buying it is not a question of price but a matter of stocks and delivery, as producers have not been able to catch up with their orders, due to the slowing up of operations of the steel mills. Prices remain unchanged. *Glycerine* has again advanced and is now being held at 16½c. The market is very firm and several large contract orders were placed at this figure recently. Another rise is not expected for the near future, but it is the consensus of the manufacturers that this price will hold for some time. *Lead acetate* is still being offered at the old schedule, however, it is rumored that an advance will take place shortly owing to the increased cost of acetic acid. *Salicylates* during the past few weeks have been moving more freely, and since our last report there has been an advance on all salicylates with the exception of *salol*, which remains unchanged. *Sulphur* is moving along at its normal rate with no change in price and no unusual business being reported. Producers of *zinc sulphate* have made a further advance in their prices, and are now quoting 3c. per lb., f.o.b. St. Louis in carlots. However, sulphate is not advancing in proportion to the increase in *spelter*, which is now being quoted at $6.20 per 100 lb., St. Louis.

VEGETABLE OILS AND NAVAL STORES

Turpentine has eased off somewhat and is being quoted today at $1.11 per gal. in 5-bbl. lots and $1.17 in single barrels. *Linseed oil* is quoted spot today at 92c. basis raw oil in 5-bbl. lots and 97c. for single barrels. This is about as previously reported. *Castor oil* has had three advances since our last report, jumping from 13¼c. to 13½@13¾c. and finally to 14c. in 400-lb. drums. This seems to be about the peak and a further rise is scarcely expected.

The Iron and Steel Market

PITTSBURGH, Aug. 18, 1922.

Steel production continues to decrease, on account of fuel conditions, and the rate of ingot production, as nearly as can be estimated, is about midway between 25,000,000 and 30,000,000 tons a year, against the rate of about 37,000,000 tons attained late in June.

The iron and steel industry derives no particular comfort from the "settlement" of the coal strike at Cleveland early in the week. The settlement itself was said to involve only about 15 per cent of the union coal capacity, and this means a smaller percentage still of the entire coal strike, for there were strikes in non-union mines, particularly in the Connellsville region, and these strikes have not been affected. Predictions are made that the Connellsville strikes will crumble within a fortnight, but these are merely predictions. The prevalent view is that among the mines formerly union the Pittsburgh district at any rate will not sign the United Mine Workers' scale but will hold out for a non-union or open shop operation, however much time may be required to attain that position.

For the nearby future at least the iron and steel industry does not expect to receive increased coal shipments and as present operations are maintained partly by stocks, now rather small, the outlook is for decreasing production of pig iron and steel.

The effect of diminishing supplies of coal is plainly observed in the production of steel, but is not apparent in the consumption of steel. It may be that consumption of steel is greatly decreased, but the evidence is not seen. Most consumers are urging mills to make heavier deliveries, and some are in the market to purchase early deliveries, which are commanding greater and greater premiums. It does not follow from the observable conditions that there are no stocks of steel in buyers' hands or that there are not large stocks in some cases, it being notorious in the steel industry that buyers endeavor to conceal their possession of steel as long as steel appears to be scarce. After every period of activity there is a spell during which consumers liquidate stocks which prove to be larger than had been assumed.

Some of the Steel Corporation subsidiaries as well as some of the independents are rationing their shipments, endeavoring to furnish steel to the more important consuming lines, while at the same time there is conservation, by denying steel to customers whose business is not of urgent character or who are unable to use the steel immediately.

ADVANCING TENDENCY IN STEEL PRICES

Steel prices show a general advancing tendency. There is not, as formerly, merely an advance in the prompt market, by the increase in delivery premiums, for basis prices, for indefinite delivery, are also advancing. An advance in the minimum on bars, shapes and plates from 1.70c. to 1.80c. was noted in last week's report. This week the American Sheet & Tin Plate Co. (Steel Corporation) has advanced its prices $2 a ton on blue annealed sheets to 2.50c. and $4 a ton on black and galvanized sheets to 3.35c. and 4.35c. respectively. The former prices had become nominal, as the company was oversold through the third quarter and had not opened books for fourth quarter. Sales are being made now chiefly to old customers. Independent pipe mills, with possibly one or two exceptions, have advanced prices on merchant pipe three points on black and two points on galvanized, a point being equivalent to about $1.90 per net ton. Some of the independent wire mills have advanced wire $2 a ton and nails 20c. a keg.

Prices for prompt delivery are not quotable, as there are various circumstances, according to the details of the individual order. An order for a tonnage of plates running into four figures has gone at 2.25c. delivery within 3 weeks.

The spot market in pig iron, the only pig iron market there is, continues to show an advancing tendency, sales being in small lots, out of stock, to urgent buyers. Foundry iron is up $2 a ton, to $30 valley, basic and bessemer being about $26 and $27 respectively, valley furnaces.

Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.15 — .17
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.30 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb.	.80 — .85
Benzoic acid, U.S.P.	lb.	.65 — .67
Benzoate of soda, U.S.P.	lb.	.53 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.22 — .25
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.33 — .35
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.21 — .22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.54 — .56
H-acid	lb.	.80 — .85
Meta-phenylenediamine	lb.	.85 — 1.00
Monochlorbenzene	lb.	.10 — .11
Monoethylaniline	lb.	1.00 — 1.20
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.07¼ — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35

Nitro-toluene	lb.	$0.15 —	$0.17
N-W acid	lb.	1.15 —	1.30
Ortho-amidophenol	lb.	2.10 —	2.15
Ortho-dichlor-benzene	lb.	.17 —	.20
Ortho-nitro-phenol	lb.	.75 —	.77
Ortho-nitro-toluene	lb.	.10 —	.13
Ortho-toluidine	lb.	.12 —	.14
Para-amidophenol, base	lb.	1.25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.72 —	.80
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	.85 —	.90
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.16 —	.18
Pyridine	gal.	1.75 —	2 75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.75 —	1.80
R-salt	lb.	.55 —	.60
Salicylic acid, tech., in bbls	lb.	.24 —	.26
Salicylic acid, U. S. P	lb.	.28 —	.29
Solvent naphtha, water-white, in drums, 100 gal	gal.	.27 —	.32
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 —	.18
Sulphanilic acid, crude	lb.	24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45

Iridium	oz.	180.00@185.00
Palladium	oz.	55.00
Mercury	75 lb.	57.00

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

GLASS—The Hart Glass Co., Dunkirk, Ind., has resumed operations at its plant, following a short curtailment due primarily to fuel shortage. It is planned to operate at full capacity with regular working force.

Owing to inability to obtain raw materials on account of the railroad strike, the B. R. C. Bottle Works, Cedar Grove, near Shreveport, La., has closed down until the situation shows improvement.

The Upland Flint Glass Co., Upland, near Hartford City, Ind., is developing maximum output at its plant and expects to run on a capacity basis at an early date. New shops are being added and additions will be made in the working force.

LEATHER—The C. P. Osborne Co., Peabody, Mass., is running practically at full capacity at its local tanning plant, with a daily schedule of production calling for about 150 doz. sheepskins, 250 splits and 300 sides of case leather. A regular working force is being employed. The plant is said to have orders on hand to insure this basis of operation for at least 3 months to come.

Glazed kid plants at Wilmington, Del., are gradually increasing production and on the general average are now working close to three-quarters of normal capacity. One local plant is running at maximum output, with full working force.

RUBBER—The Firestone Tire & Rubber Co., Akron, O., is arranging for the early operation of its new plant at Hamilton, Ont., now nearing completion, and will run on a basis of about 1,500 tires per day for a number of weeks. This output will be increased closely following thereafter.

The B. F. Goodrich Co., Akron, O., is pushing production at its local plant, and expects to exceed the current daily output of 20,000 tires, recently established, at an early date.

The Kelly-Springfield Tire Co., Akron, and Wooster, O., is maintaining operations at its local mills on a capacity basis with full working force. It is expected to continue on this schedule for an indefinite period.

Following a reduction in the price of tires the Miller Tire & Rubber Co., Akron, O., is said to have received a quantity of heavy orders necessitating an increase in the current production of 7,500 tires per day, recently established. The advance will be made at an early date, with increased working force.

IRON AND STEEL—The Brier Hill Steel Co., Youngstown, O., has resumed operations at its plate mill, known as Mill No. 132, giving employment to about 150 men, following a curtailment for the last 60 days.

The American Sheet & Tin Plate Co., Elwood, Ind., has resumed operations at all of its local hot mills, forced to shut down recently on account of fuel shortage. It is expected to maintain continuous operations for an indefinite period.

The Gulf States Steel Co., Gadsden, Ala., is running full at its local finishing mills. Four open-hearth furnaces are now in service at the plant.

Owing to fuel shortage, the Phœnix Iron Co., Phœnixville, Pa., has been compelled to shut down its local furnaces, affecting about 150 employees. It is expected to resume as soon as possible.

The Inland Steel Co., Chicago Heights, Ind., has curtailed operations at its hard steel bar mill owing to a strike of employees, who have asked a wage advance of 20 per cent. A portion of the plant of the Calumet Steel Co., in the same district, has also been closed on the same account. About 900 men are out at the present time.

The Wheeling Steel & Iron Co., Benwood, W. Va., has closed down its local mills, following operations for a number of weeks on an 80 per cent capacity basis. It is said that the curtailment is due to the railroad and coal strikes. About 250 men are affected.

As a result of the railroad and coal strikes, the United States Steel Corp. has reduced operations at its mills in the Chicago, Ill., district from 84 to 78 per cent of capacity. The corporation is concentrating on blast furnace operations at its plants in the Youngstown, O., district in order to furnish material to the rolling mills of the American Sheet & Tin Plate Co. Its subsidiary, the Carnegie Steel Co., is maintaining production at ten blast furnaces in the Youngstown section.

The Glasgow Iron Co., Pottstown, Pa., has resumed operations at all departments at its local mills on a capacity basis, giving employment to a regular working quota. Continuous operation is assured for a long period due to large reserve coal supply.

The Janson Iron & Steel Co., Columbia, Pa., has closed down its local mills owing to fuel shortage. The Columbia Rolling Mill of the Reading Iron Co., at this place, is continuing production and has sufficient fuel to run for a few weeks.

The Weatherly Iron & Steel Co., Weatherly, Pa., is operating on a full-capacity basis, and has more orders on hand than for several years past. The plant is shipping on an average of 10 carloads of finished products per week.

The Colorado Fuel & Iron Co., Pueblo, Colo., is curtailing operations at its mills, and about 1,500 men have been released recently. The plant is now giving employment to more than 4,500 operatives.

The Republic Iron & Steel Co., Youngstown, O., is arranging for the use of fuel oil in its open-hearth department, instead of coal, and will fire a number of units at an early date.

The Carnegie Steel Co. has banked all departments at its Farrell Works, Sharon, Pa., with the exception of one blast furnace, affecting about 1,200 men.

MISCELLANEOUS—The Kinzer Brick Co., Ephrata, Pa., has adopted a capacity basis of production at its local plant, giving employment to a full working force.

The Norton Co., Worcester, Mass., manufacturer of abrasive products, is resuming operations at its branch plants at Niagara Falls, N. Y., and Chippawa, Ont., following an extended shut down. Each plant will give employment to about 200 men for initial operations.

Foundries at Sandusky, O., are now running at close to normal production, giving employment to regular working forces.

Owing to fuel shortage, the American Zinc Products Co., Greencastle, Ind., has closed a number of departments at its local mills.

Construction and Operation

Alabama

KEYSTONE—The Keystone Lime Works, Inc., recently organized, has obtained a local plant building and will soon begin the installation of hydrating and operating machinery for a daily capacity of about 1,000 bbl. of lime. The equipment for the most part will be electrically operated. W. A. Hammond, Saginaw, Ala., and George L. Scott, Longview, Ala., head the company.

GADSDEN—The Tri-City Gas Co. will begin at once the installation of a new gas producer and auxiliary machinery at its local plant.

California

TURLOCK — The Hunt-Jewett-Bontz Co., South 1st St., has completed plans and will soon break ground for the construction of a new local plant for the manufacture of industrial alcohol and kindred products. It will consist of a main 4-story factory, with 1-story structure adjoining, estimated to cost about $175,000. The machinery installation will cost in excess of $225,000 in addition to the amount noted.

SAN FRANCISCO—The Illinois Glass Co., San Francisco, manufacturer of hollow ware, bottles, etc., has leased a 2-story building, 124x200 ft., on Mariposa St., near Alabama St., for which plans are now being prepared. It is estimated to cost $125,000. It is planned to have the structure ready for occupancy at an early date.

Connecticut

DANBURY — The Metropolitan Concrete Block Co. has plans under way for the establishment of a new plant for the manufacture of brick, to be operated in conjunction with a recently established works for the production of concrete blocks. A number of kilns will be constructed and machinery installed for a large output. Charles Woods is in charge.

HARTFORD—The Skat Co., Francis Ave., manufacturer of soaps, soap powders, etc., has awarded a contract to Wise & Upson, Inc., for the construction of its proposed 1-story plant addition, 46x61 ft. Work will be commenced at once. F. C. Walz, Hartford, is architect.

WALLINGFORD—The Wallingford Steel Co., recently organized with a capital of $200,000, is arranging for the early occupancy of its new local plant, now in course of completion. Initial production will be devoted to cold-rolled steel products. The new works is said to represent an investment of approximately $75,000, and will be extended at a later date.

MANCHESTER—The Oxford Soap Co., Hilliard St., has awarded a contract to the H. P. Cummings Construction Co., Ware, Mass., for the construction of a new 2- and 3-story plant addition, 70x150 ft., to be used for general manufacture.

MILFORD—The Hoyt Silver Co., New York, N. Y., recently organized by William T. Hoyt, 9 Maiden Lane, and now operating a small plant at 338 Pearl St., is planning for the early establishment of a new plant at Milford for the manufacture of a special stainless metal. The initial works will give employment to close to 300 persons.

Florida

LAKE WORTH—F. E. Bryant, Lake Worth, is organizing a company to construct and operate a sugar-refining plant. A tract of 11,000 acres of land has been acquired in Palm Beach County, to be used for the plant's site, and for sugar cane plantations. It is planned to commence operations at an early date.

Indiana

INDIANAPOLIS — The Board of Sanitary Commissioners, City Hall, E. B. Swift, president, has plans under way and will call for bids at an early date for the construction of a new purification plant at the city water works, 1-story, 100x140 ft., estimated to cost $530,000, including equipment. Charles H. Hurd, 1405 Merchants Bank Bldg., is engineer.

INDIANAPOLIS—The Beveridge Paper Co., Pearl St., has filed plans for the construction of a new plant addition, adjoining its present works, estimated to cost close to $50,000. H. L. Beveridge is president.

HAMMOND—The Metals Refining Co., 627 Hohman St., has awarded a contract to Rowley Bros. Co., 332 South LaSalle St., Chicago, Ill., for the construction of a new 1-story and basement building on Summer St., 38x50 ft., estimated to cost about $35,000.

INDIANAPOLIS—The Chapman-Price Steel Co., Shelby St., will hold in temporary abeyance the construction of its proposed new local steel mill, comprising a number of buildings, estimated to cost about $500,000, with equipment. It is expected to commence erection some time during the coming year. Niles Chapman is president.

KOKOMO—The Mileage Oil Refining Co., comprising a recently consolidation of the Service Oil & Refining Co., the Hoosier Oil Co. and the Iroquois Oil Co., is planning for the early operation of its oil refinery at Fairmount, Ind., and will develop a capacity of 1,200 bbl. per day. The company has arranged for an increase in capital from $100,000 to $800,000, and will use a portion of the proceeds, it is said, for extensions and improvements in the plant, including the construction of a number of service buildings. J. C. F. Martin is president; and S. W. Winder, Marion, Ind., is secretary and treasurer.

Illinois

CHICAGO — The International Harvester Co., 606 South Michigan Ave., will commence the immediate construction of a 1-story, open-hearth furnace building at its Wisconsin steel works, Torence Ave. near 110th St., to be 143x500 ft., estimated to cost $360,000. The general contract has been let to the Bates & Rogers Construction Co., 37 West Van Buren St.

Louisiana

SHREVEPORT—The Southern Soap Co., Box 602, recently organized with a capital of $100,000, has plans under way for the con-

struction of a local plant for the manufacture of soaps, soap powders and kindred specialties. Work will be commenced at an early date. A list of equipment to be installed will be arranged at once, and bids called early in September. W. A. Vickers is president and general manager.

WINNFIELD—A. C. Campbell, Winnfield, is organizing a company to construct and operate a local plant for the manufacture of concrete blocks, tile and kindred productions. It is proposed to commence work at an early date.

Maine

BRIDGTON—Fire, Aug. 6 damaged a portion of the plant of the Sims Leather Co., with loss estimated at close to $13,000.

Maryland

BALTIMORE — The Bethlehem Steel Corp., Bethlehem, Pa., will commence the immediate construction of an addition to its local plant in the Sparrows Point district, estimated to cost in excess of $3,000,000, with equipment. The work will comprise a number of new open-hearth units with subsidiary departments, to provide for an increase of close to 5000,000 tons of steel ingots per annum. Eugene G. Grace is president.

Michigan

MONROE—The Republic Glass Co., Kentucky Ave., will commence the immediate construction of a new 1-story plant, 200x400 ft., for the manufacture of general glass products, estimated to cost about $50,000, exclusive of equipment. Emanuel Llera is president.

Minnesota

ST. PAUL—The Flaxlinum Insulating Co., Hampden and Wabash Aves., manufacturer of insulating products, plans for the rebuilding of the portion of its works recently destroyed by fire.

Missouri

ELDORADO SPRINGS—The Eldorado Development Co., recently organized with a capital of $300,000, has acquired a tract of about 320 acres of land, and plans for the establishment of a new zinc plant. It is proposed to provide a capacity of approximately 300 tons per day. A list of equipment for installation is being arranged, and it is expected to call for bids during September. A. B. Stricklett is president and general manager.

North Carolina

PINE HALL—The Pine Hall Brick Co., recently organized, has acquired the plant and property of the Dan River Brick Co., comprising about 125 acres of land, and will inaugurate operations at an early date. Plans are said to be under way for extensions and improvements. C. L. Lester is general manager.

CHARLOTTE—The City Council is taking bids until Aug. 29 for the construction of a new filtration plant at the municipal water works, estimated to cost about $300,000. William Platt, Durham, N. C., is consulting engineer. Edgar Reade is city clerk.

COLON—The L. C. Isenhour Co. has preliminary plans under consideration for the construction of a local plant for the manufacture of brick, tile and kindred burned clay products.

RALEIGH—The City Council has plans in preparation for the construction of a new filter plant at the city waterworks, to include an electrically operated pumping station, estimated to cost about $150,000. Bids will be asked in September. J. B. Bray, chairman of the Board of Public Works, is in charge. William C. Olsen, Kinston, N. C., is consulting engineer.

New Jersey

LINDEN—The Superior Novelty Mfg. Co., 124 East Jersey St., Elizabeth, N. J., manufacturer of celluloid and fiber products, has awarded a contract to H. Wilhelms & Sons, Inc., Elizabeth, for the construction of a new 1-story plant, 50x200 ft., on Edgar Road, Linden, to cost approximately $50,000. William Finne, 712 1st Ave., Elizabeth, is architect.

New York

LONG ISLAND CITY—The National Liquid Bleach Co., 18 Purvis St., has acquired an entire block front of property on Foster Ave. between Honeywell and Buckley Sts., as a site for a new plant. Plans will be prepared at once and construction commenced at an early date.

NEW YORK—The Tidal Refining Co., 11 Broadway, a subsidiary of the Tidewater Oil Co., with headquarters at the same address, has appropriated a fund of $1,000,000 for extensions and improvements in its oil refineries and gasoline extraction plants in Oklahoma and Kansas. The company is now operating 2 oil refineries and 22 gasoline plants. Considerable new equipment will be installed.

NEW YORK—Fire, Aug. 8, destroyed a portion of the plant of W. H. Dong & Co., 244 Canal St., manufacturers of coloring products for foodstuffs, etc., with loss approximating $12,000. It is proposed to replace the damage at an early date.

Ohio

TOLEDO—The Toledo-Libbey-Owens Sheet Glass Co., a subsidiary of the Libbey-Owens Sheet Glass Co., Nicholas Bldg., has completed plans and will break ground at once for the construction of a new local plant for the manufacture of sheet glass products. The initial works will comprise a number of buildings, with tanks, electric power plant, etc., and are estimated to cost close to $3,000,000, including equipment. The company is capitalized at $6,000,000, and has arranged for the sale of a preferred stock issue of $3,000,000 to finance the construction.

MIDDLETOWN—The Gardner-Harvey Paper Co. will soon take bids for the construction of a new 1-story and basement plant addition, 200x400 ft., estimated to cost approximately $130,000. E. T. Gardner is president.

Oklahoma

ARDMORE—The Amerada Petroleum Corp. has acquired property in the Amerada Pool district as a site for the construction of a new absorption gasoline plant, to have a capacity of 4,500,000 cu.ft. Plans will be prepared at an early date.

Pennsylvania

GREENVILLE—The Greenville Steel & Iron Co., care of the Greenville Chamber of Commerce, has plans in progress for the construction of a new plant on local site for the manufacture of steel products. It will comprise a number of buildings including four 60-ton open-hearth furnaces, and one 10-ton open-hearth furnace, the latter to be used in connection with experimental work; blast furnace; four rolling mills; cold drawing mill, etc. A 15,000-hp. power plant will also be built. A feature will be made of the manufacture of electric steel castings. The plant will have an initial output of close to 300,000 tons a year, and is estimated to cost approximately $2,000,000. General offices will be located at Greenville. Colonel H. P. Bope, formerly connected with the Carnegie Steel Co., Pittsburgh, heads the company, which was recently organized. H. E. McConnell will be managing director.

PHILADELPHIA—The Henry Bower Chemical Mfg. Co., 29th St. and Grays Ferry Road, specializing in the production of ammonia and kindred products, has filed plans for the construction of an addition to its plant to cost about $25,000. Alterations will be made, also, in one of the existing buildings at the works.

NEW CUMBERLAND—Albert Hanker, operating a local box-manufacturing plant, is perfecting plans for the construction of a new plant in the vicinity of Second and Reno Sts., to be equipped for the manufacture of glazed paper products.

TEMPLE—The Stalium Metals Co., recently organized to manufacture special metals, will commence construction at once of a new local plant to comprise a number of buildings, estimated to cost about $200,000 S. S. Staley heads the company.

Texas

YOAKUM—The Texas Hide & Leather Co. has plans under way for the construction of an addition to its plant to cost about $17,000. Improvements will be made also in the existing works.

RANGER—The Texas-Pacific Coal & Oil Co. has acquired property near Caddo, Tex., as a site for a new gasoline absorption plant, estimated to cost about $100,000, including equipment. Work will be commenced at an early date.

DALLAS—The Allied Chemical Co. is completing plans and will soon break ground for the construction of a 2-story plant at Alma St. and Santa Fe Ave., 40x125 ft., to include a power plant, office and other miscellaneous structures. Initial production will be devoted to boiler compounds and other chemical products. The new plant will cost close to $50,000. W. R. Sparkman is president; and H. H. Howard, vice-president and general manager.

Virginia

HOPEWELL — The Hummel-Ross Fibre Corp. has preliminary plans under consideration for the construction of a number of new plant buildings at its local mill, to be equipped for general production and finishing operations. It is said that the plant will cost in excess of $175,000, including equipment.

Washington

SEATTLE—The J. W. Fales Paper Co. has plans under way for the construction of a new 3-story building at its plant, to cost about $35,000.

West Virginia

HUNTINGTON—The Superior Glass Products Co., Adams Ave. and 19th St., has tentative plans under consideration for the rebuilding of the portion of its plant destroyed by fire, Aug. 2, with loss approximating $150,000, including equipment.

HUNTINGTON—The Eureka Rubber Preserving Co., recently organized with a capital of $400,000, has plans in progress for the construction of a new plant on local site for the manufacture of rubber preservatives, primarily for automobile tire service. The works will include a large experimental laboratory. L. C. Basham is general manager.

New Companies

THE ARTHUR A. LEHMAN CO., New York, N. Y., care of J. Q. Perry, 84 William St., representative, has been incorporated with a capital of $12,000, to manufacture chemicals and chemical byproducts. The incorporators are J. C. Treadwell, A. A. Lehman, and W. T. Easley.

THE SYNTHETIC LEATHER CORP. OF AMERICA, Scotch Plains, N. J., has been incorporated with a capital of $1,000,000 to manufacture paints and affiliated products. The incorporators are R. O. Lipton, Rufus Delafield, and Frederick J. Balmer, Scotch Plains.

THE BALTIMORE WATER PAINT CO., 942 Madison Ave., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture paints and affiliated products. The incorporators are Herbert C. Metcalfe, I. Brenner, and Albert H. Samuel.

THE FELSTONE CO., Asheville, N. C., has been incorporated with a capital of $100,000, to manufacture pottery and other burned clay products. The incorporators are G. C. Reiniger, C. Marshall Gravatt, and Blair Taylor, all of Asheville.

THE CLAIR CHEMICAL CORP., New York, N. Y., care of J. I. Wiener, 1482 Broadway, New York, representative, has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are W. A. Miller, R. L. Noah, and L. Rothschild.

THE STATE REFINING CO. INC., Dallas, Tex., has been incorporated with a capital of $400,000, to manufacture refined petroleum products. The incorporators are Shearon Bonner, S. F. Semo, and F. B. Horton, all of Dallas.

THE ROY RUBBER CO., 221 East Hanover St., Trenton, N. J., has been incorporated with a capital of $100,000, to manufacture rubber products. Edward L. Royal, address noted, is the principal incorporator, and represents the company.

THE EBERLING BRICK & TILE CO., Detroit, Mich., has been chartered under state laws, to manufacture brick, tile and other burned clay products. The incorporators are William Lucking, James W. Thomas and Howell Van Auken, 1502 Ford Bldg., Detroit.

THE DE COTTIS CHEMICAL & COLOR CO., Pittsburgh, Pa., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts, colors, etc. C. Schoemer, 408 Union Arcade, Pittsburgh, is treasurer.

THE LUSTERINE POLISH CO., 2212 West Harrison St., Chicago, Ill., has been chartered under state laws, to manufacture polishes, cleaners, etc. The incorporators are William D. Sheppard and John Schouten.

THE WATSON CHEMICAL CO., Lebanon, Mo., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are C. O. McCain, C. G. and E. I. Watson, all of Lebanon.

THE BOONTON MOULDING CO., Boonton, N. J., has been incorporated with a capital of $50,000, to manufacture composition products, moulded materials, etc. The in-

corporators are Frank H. Pierce and George Scribner, Myrtle Ave., Boonton.

THE WYOMING & MONTANA OIL CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $1,000,000, to manufacture petroleum products.

THE RED DIAMOND CHEMICAL CO., Philadelphia, Pa., care of Biddle, Paul, Dawson & Yocum, 505 Chestnut St., Philadelphia, representatives, is being organized by Calvin M. Smyth and Woodward K. Greene, to manufacture chemicals, chemical compounds, oils, etc. Application for a state charter will be made on Sept. 5.

THE MARSHALL METAL CORP., 2608 South Wells St., Chicago, Ill., has been incorporated with a capital of $100,000, to operate a metal fabricating works for the production of aluminum, steel, brass and other metal products. The incorporators are Frank E. Chamberlain, John J. Stream, and John R. Marshall.

THE HAMILTON LEATHER PRODUCTS CORP., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $250,000, to manufacture leather products.

THE PEERLESS LIQUID CEMENT CO., New York, N. Y., care of Stern & Stern, 49 Chambers St., representative, has been incorporated with a capital of $5,000, to manufacture liquid cements and affiliated products. The incorporators are J. Keeler, and S. Lange.

THE TOLEDO ALUMINUM & BRONZE CASTINGS CO., Toledo, O., has been incorporated with a capital of $10,000, to manufacture aluminum, bronze, brass and other metal castings. The incorporators are Otto K. Rudon and Charles M. Kistner, both of Toledo.

THE WHARTON COUNTY OIL MILLS, INC., El Campo, Tex., has been chartered under state laws to operate a local mill for the manufacture of cottonseed oil products. The incorporators are H. E. Wilson, A. L. Lawson, and Hans Goldmann, all of El Campo.

THE BURWALL CHEMICAL CORP., New York, N. Y., care of Tison & Melick, 15 William St., representatives, has been incorporated with a capital of $500,000, to manufacture chemicals and chemical by-products. The incorporators are M. Wittlan, E. J. Russo, and E. C. Beekmann.

HERRMANN, MORRIS & CO., 878 Mt. Prospect Ave., Newark, N. J., has filed notice of organization to manufacture dry colors, chemical specialties, etc. Edwin Blum, 44 West 70th St., New York, N. Y., heads the company.

THE INLAND GLASS CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws, with a capital of $1,500,000, to manufacture glass products.

THE FALOR RUBBER CO., 910 South Michigan Ave., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture rubber products. Shelby A. Falor is president; and C. F. Schnee, secretary.

THE CARNAHAN PRODUCING & REFINING CO., San Antonio, Tex., has been incorporated with a capital of $25,000, to manufacture petroleum products. The incorporators are Henry C. King, Jr., Clinton Chenault, and J. E. Carnaham, all of San Antonio.

THE RELIABLE GAS & OILS, INC., Newark, N. J., has been incorporated with a capital of $50,000, to manufacture and deal in lubricating oils, etc. The incorporators are Hugh F. Gilligan, Harry B. O'Connell, and William F. Haas, 1212 Broad St., Newark.

THE ATLANTA GLASS MFG. CO., Atlanta, Ga., has been incorporated with a capital of $500,000, to manufacture glass products. The company has plans under way for the erection of a local plant. F. J. Cooledge, Jr., Atlanta, is president.

THE AMERICAN OPALOGRAPH CORP., Long Island City, N. Y., care of Weller & Rogers, Jamaica, L. I., representatives, has been incorporated with a capital of $100,000, to manufacture chemicals and chemical by-products. The incorporators are F. J. Klein, C. H. Senior and H. D. Snyder.

THE GRADY BRASS CO., Wilmington, Del., care of the Corporation Service Co., Equitable Bldg., representative, has been incorporated with a capital of $10,000, to manufacture brass and bronze products.

THE UNITED HIDE CO. OF NEW JERSEY, Newark, N. J., care of Harold Simandl, 418 Kinney Bldg., representative, has been incorporated with a capital of $100,000, to operate a local tannery. The incorporators are M. R. Gibney, Leo D. Schwartz and Mark Herbst.

THE RADIO-TONE CHEMICAL CO., New York, N. Y., care of Leon Bleecker, 249 West 34th St., representative, has been incorporated with a capital of $10,000, to manufacture chemicals and chemical by-products. The incorporators are E. G. Coundjeris and E. G. Manias.

THE ALLYNDALE LIME CO., Southington, Conn., has filed notice of change of name to the CAINE LIME CO.

Manufacturers' Catalogs

BAKER & CO., INC., Newark, N. J., has issued its fourteenth edition of "Data Concerning Platinum," which contains new tables, illustrations and matter descriptive of various appliances made of platinum.

THE EAST JERSEY PIPE CO., Paterson, N. J., in a new pamphlet, Bull. X203, illustrates and describes Type B Hercules electric hydro-extractors.

THE BARRETT CO., New York, has issued a booklet on Barrett Flotation Oils and Reagents.

THE LINK-BELT CO., Chicago, is issuing literature on the Link-Belt crawler crane, which is the newest machine from this company's Chicago shops.

THE CONNERSVILLE BLOWER CO., Connersville, Ind., in order to more completely describe its line of small blowers, has just issued Bulletin 21, on Victor Positive Pressure Blowers.

THE SCHUTTE & KOERTING CO., Philadelphia, Pa., has issued a very attractive catalog entitled "Koerting Fuel Oil Burning Systems." It consists of three bulletins which describe mechanical fuel oil-burning systems and fuel oil burners in which the oil is atomized by low- or high-pressure air and steam. It discusses thoroughly the installation, operation and maintenance of oil-burning equipment, its characteristics, requirements and functions, the relative merits of mechanical and spray oil burners, the design, purpose and operation of air control registers, oil-pumping outfits, duplex oil strainers and fuel oil heaters, the general requirements of steam boiler furnaces for burning oil, operation, inspection of the system, lighting the fires, air for combustion, indication of satisfactory operation, number and arrangement of burners, effects of carbon deposits and soot, etc. The catalog is profusely illustrated in color.

THE ELECTRIC FURNACE CONSTRUCTION CO., Philadelphia, Pa., has published two new catalogs. "Electric Furnaces for Melting, Refining and Superheating of Iron and Steel" describes various types of electric furnaces and particularly a new feature of the "Greaves-Etchells" steel melting furnace applied to four or more electrode furnaces. This system permits of all the electrical power being put either entirely through top electrodes or, by change of position of the switch, through top electrodes and through the whole of the furnace hearth, each connection being so arranged as to give a balanced load and a high power factor. This gives a very flexible electric melting unit, having all the advantages of top electrode furnace for melting down, and top and bottom heat for the refining and addition of alloys and finishing off. This bottom heat has been found extremely beneficial during these latter operations, giving as it does slow circulation of the molten bath from the bottom, uniform temperature throughout, and a homogeneous finished product. The other catalog describes the "Electro" steam boiler, developed by F. T. Kaelin, chief engineer of the Shawinigan Water & Power Co. These electric steam boilers take high tension current direct and use the water itself as a resistance. These boilers have a thermal efficiency of over 98 per cent and a unity power factor, and should be of interest to all hydro-power companies or consumers of power who pay on peak or connected load basis.

THE BROWN INSTRUMENT CO., Philadelphia, Pa., announces the publication of a new resistance thermometer catalog which explains the theory of resistance thermometry, the various type of instruments which are made and the merits of each type. Copies will be send to any executive on request.

THE CORNING GLASS WORKS, Corning, N. Y., has issued a pamphlet on Pyrex Industrial Glassware, which is a preliminary announcement of a new stage in the evolution of Pyrex glass, in the application of Pyrex to chemical plant uses. In the pamphlet is a brief description of three typical shapes, with dimensions, prices, etc., and the following are articles either in production or in the final experimentage stage: Socket pipes and bends, "S" bends for cooling and condensation work, pipe lines made of large bore tubes, tubes for catalytic re actions, retorts for distillations, etc., evapo rating dishes, flat pans for driers, etc., re ceivers for hot liquids, flat sheet glass an sight glasses and sight pipe sections. Som of the outstanding features of this glass ware are also given.

THE OLIVER-SHERWOOD CO., San Fran cisco, Calif., announces a new bulletin o "Olivite" centrifugal pumps, which ar especially designed for rigorous service i chemical industries. The pump is not hard rubber pump, but it is of acid-proo character due to a new composition whic has a rubber basis, and is adapted to han dling and pumping of dilute solutions o hydrochloric, nitric, sulphuric and phos phoric acids.

THE DELAVAL STEAM TURBINE CO., Tren ton, N. J., in a 28-page catalog illustrate and describes a line of velocity stage tur bine especially designed for high-pressur and high-temperature steam. The cast ste steam chest is located in the casing cove in order to avoid the conduction of heat t the bearings. In addition to the speed gov ernor and governor valve, there is an in dependent valve controlled by an automati over-speed trip. The turbines are built i sizes up to 1,200 hp., and are designed t be directly coupled to high-speed centrifu gal pumps and blowers, small a.c. and d.c generators, and by means of double helica speed reducing gears, to large pumps an blowers, medium size generators, belt pul leys, rope sheaves and slow and moderat speed machinery.

THE WESTINGHOUSE ELECTRIC & MFG. Co East Pittsburgh, Pa., in Circular 1579-B, o "Micarta Gears and Pinions," describes th development of this material, which is non metallic, for gear and pinion applicatio that can be advantageously substituted fo untreated steel, cast iron, bronze and al other materials used for gearing. It is laminated product of specially treate woven fabric and can be machined in th ordinary manner. This material was de veloped to meet the demand for silent gea drives. The company also states that it i not attacked by rodents and vermin; is no affected by water or oil, or by most aci and alkali solutions; can be kept in storag indefinitely without deterioration and is ap plicable to a great many special construc tions. The catalog contains general in formation and technical data for cuttin micarta gears and pinions.

Coming Meetings and Events

ALPHA CHI SIGMA dinner, during th Chemical Exposition, will be held Thursday Sept. 14, at 6:30 p.m. at Keen's Chop House 107 West 44th St., New York City. Mem bers are requested to register at *Chem. & Met.'s* booth at the Exposition.

AMERICAN CHEMICAL SOCIETY will hol its fall meeting in Pittsburgh, Pa., Sept. to 9.

AMERICAN ELECTROCHEMICAL SOCIETY wil hold its fall meeting in Montreal, Sept. 21 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold it annual convention and exhibition at Atlan tic City, Oct. 23 to 28.

AMERICAN INSTITUTE OF MINING AN METALLURGICAL ENGINEERS will hold it 126th meeting at San Francisco, Calif., Sept 25-29, 1922.

AMERICAN SOCIETY FOR STEEL TREATIN will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

ASSOCIATION OF IRON AND STEEL ELECTRI CAL ENGINEERS will hold its sixteenth annual convention Sept. 11 to 15 at Cleve land Public Hall, Cleveland, Ohio.

NATIONAL EXPOSITION OF CHEMICAL IN DUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AN MECHANICAL ENGINEERING will be held a the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL SAFETY COUNCIL will hold it Eleventh Annual Safety Congress in De troit, Aug. 28 to Sept. 1.

NEW JERSEY CHEMICAL SOCIETY has dis continued meetings for the summer, bu will resume them in October.

SOCIETY OF INDUSTRIAL ENGINEERS wil hold a 3-day national convention in New York, beginning Oct. 18. The general topi of the convention is "Economics of Indus try."

The Theme of This Issue— Increased Production Efficiency

PSYCHOLOGISTS tell us that sustained emotion is harmful and beyond a certain point impossible. That is why a man viewing Niagara for the first time is awed, whereas the bellboys at Hotel Clifton hardly ever glance at the spectacle. We, you, in our relation to the chemical industry are much like the Clifton bellboys with respect to Niagara. Our contact is so close, so continuous, that we are likely to look upon it only in the most casual manner. For this reason it is worth while occasionally to detach ourselves and view the whole spectacle or a part of it with the enthusiasm of a novice. The thrill may not and will not be sustained, but it will have the inestimable value of orienting us anew and lifting us out of the rut of routine.

Such is the purpose of this issue of *Chemical & Metallurgical Engineering*. Speaking in all modesty for ourselves, but with full credit to the excellent authors who have contributed the contents, we think the issue serves the purpose of taking the reader away from the routine of his task and directing his attention in a most inspiring manner to a special topic of undoubted importance.

Why seek to increase the efficiency of our production processes?

Production and distribution, their interrelations and their influence on human affairs, constitute in large measure the problems which our civilization is now facing. Between these two factors there can be no choice as to which is more important. If the world as we know it is to continue to develop along its present paths, then ultimately both of these problems must receive as nearly perfect a solution as is within the compass of human ability. The question of importance between these two factors is one of immediacy.

As the population increases and the free natural resources of the world diminish, the pioneer type of independent existence becomes possible to an ever-decreasing number. More and more we depend on cheap and rapid production of goods—quickly and efficiently distributed—for the maintenance of our well being and happiness.

The problem of distribution must be solved. If it is not, our ability to obtain the necessities and luxuries by which our standard of living and our very civilization are maintained will lessen. If it lessens to any great extent, the whole structure of our life as we know it will tumble about our ears, as it recently did in Russia. Only through efficient, scientifically administered distribution can the spread between the producer and the consumer be kept down. The development of this administrative control is largely a matter of government, and for this reason must unfortunately wait on politics. In the long run, however, the public at large has government under its control and can, when educated to the point of realizing the necessity of good distribution methods, demand and get them.

Efficient distribution, although it may seem extraneous to our main editorial theme, is nevertheless so closely tied up to the problems of production that we have felt justified in giving it some consideration at this time. With this end in view we have included a series of short, poignant messages from leading sales executives outlining their views as to how efficient production can be supported by better directed and more intelligent distribution.

Efficient production is fully as important to our way of life as is good distribution. The advent of the machine made possible a vast extension in quantity and kind of the goods by which mankind lives. Machinery on the farm increased the available food supply, and machinery in the town increased the supply of those goods which the farmers needed and for which they were willing to exchange food. The age-long checks were removed, the doctrine of MALTHUS for the time ceased to operate and the population of the world increased by bounds. Such a situation cannot continue indefinitely. There must come a time when the most strenuous efforts of all workers will not serve to keep up the standard of living requisite to well being, even with the improvements in method and equipment which will without doubt then be available. The limit of exploitation of the earth's resources will eventually be reached and the law of MALTHUS must then operate.

The earth's resources are still ample to keep all in comfort. The scientific knowledge for their development is available. Man's ineptitude alone is responsible for the problems of adequate production which the world now faces and upon the solution of which so largely depend the welfare and contentment of the race and the dissipation of the ugly unrest so prevalent today.

Production need not delay, as distribution must, the solution of its problems. The power to reach these solutions lies today in the hands of the technologists, engineers, executives and owners who control our industries. Every consideration of successful business, the highly competitive market which must be met, the demands of labor and the demands of capital, all these strongly urge them to exercise this power. If those at present in control do not increase the efficiency of production, then their places must be taken by those that will. For the means of effecting this increase in production efficiency are at hand and the lower prices that will result are the first step that must be taken in restoring the balance of our war-tried world.

With these facts in view, we have gathered in this issue the thought of some of the country's industrial leaders on the present industrial situation and their recommendations as to the paths to be followed to reach an improved condition. The articles in which their thoughts are embodied form a message which cannot fail to be of inspiration and benefit to all connected with productive industry—a message of INCREASED PRODUCTION EFFICIENCY.

The Human Factor in Efficient Production

HUMAN EFFORT lies at the very foundation of production, and yet of the entire structure it is the least tangible part. Even in our industries where science and engineering have evaluated machine and process with all the precision of mathematical certainty, there still remains the human element, the unknown quantity, the x in every equation. That intangible something which eventually finds its way into the profits and losses of industry touches on every phase of production, distribution and management. It offers a myriad of problems, many as old as industry itself. But it is in the intricacy of modern business that we find most evidence of its workings, and it is there that we should study it. The age-old problems of employer and employee have so broadened that the manager of today is concerning himself with many questions which a few years ago were regarded as foreign to industry's obligations. Such factors as the health and happiness of the workers, their welfare and safety, physical and mental comfort, housing and sanitation, selection and training—all these are now recognized as just as much the problem of management as those of supervision, wages and hours of work.

But underlying all of this is the fundamental conception of labor—not as a commodity subject to impersonal barter and trade, but as a vital, living force sharing with capital in the ups and downs of industry. When the Secretary of Labor tells us, as he does in this issue, that the American workman is coming to realize his tremendous responsibility to himself, his craft, his industry and his country, Mr. DAVIS is speaking for an enlightened citizenry. And certainly labor must look far to find a more creditable spokesman. Coming to this country as a youngster in a large family of Welsh immigrants, JAMES J. DAVIS began a most unusual career, and yet one that is typically American. He was only 11 when he entered the steel mill to learn his trade as a puddler, and there for 14 years he worked at severest manual labor. Naturally, with such a grounding, the Secretary of Labor looks at industry through the eyes of labor, but not with the bias of the partisan nor the prejudice of the professional organizer. His message on "Labor's Responsibility for Industrial Efficiency," which was written specially for this annual number of *Chemical & Metallurgical Engineering*, sounds the opening note in our editorial appeal for INCREASED PRODUCTION EFFICIENCY. It has been given this position of honor because we regard it as a classic on which labor may well rest its case.

"Wages" is one of the shortest and simplest words of our language, but it is of tremendous connotation. Concretely, it expresses all of the contractual relations existing between employer and employee. HARRINGTON EMERSON, in his contribution on this subject, gets at the very fundamentals on which wage payments are based. In tracing these relations from Biblical to modern times, he derives four great fundamental principles which he holds essential to the ideal wage system.

Labor turnover—what employer is there who hasn't reason to give it thought? PHILIP BRASHER is inclined to believe that excessive labor turnover is resulting in greater loss to the average manufacturer than is the strike or the lockout. But in either case the cause is the same—the lack of harmonious relations between the employer and the employed. Our contributor offers a solution to this problem in just one word—contact.

Health and happiness of the worker are paramount considerations of the thoughtful employer. JOHN S. SHAW'S experience in one of our largest industries leads him to the conviction that the promotion of these factors favorably affects production and costs. To his way of thinking, the manager can profitably spend as much time and money advancing the comfort and contentment of his workers as in the solution of the physical and technical problems of production. Mr. RESNICK, of the Safety Institute of America, would add safety to this category. Although the industrial safety movement had its inception in a purely humanitarian appeal, it has demonstrated over and over again that to safeguard life and limb is to sidestep a costly drain on morale, production and profit. The progressive manufacturer will find in this article many thoughtful suggestions for removing the hazards of production.

A keener sense of one's place in industry and a better understanding of production principles will make any employee more valuable to his employer. But B. M. NUSSBAUM, in his article on industrial training, would concentrate on the foreman, who he believes holds the most strategic position in the plant organization. By teaching these key men to pull together, it is possible to build up a loyalty that will solve many of the problems of management, that will lower costs, eliminate waste and increase production.

Doubtless there are many other problems of production that turn on the human element. But their solution is not radically different from those which we have already advanced. The whole matter can be summed up in no better way than in a single sentence from Secretary DAVIS' message: "The highest efficiency will be reached by that industry in which the employer knows intimately the problems and needs and aspirations of the worker, and in which the worker has a sympathetic understanding of the difficulties and discouragements and purposes of the employer."

Some Economic Angles To Production Efficiency

IN A recent issue of the *American* magazine there appeared an interview by a versatile and pleasing writer, BRUCE BARTON, with a real leader of industrial progress, HENRY DENNISON, president of the Dennison Manufacturing Co. The interview made a profound impression, partly because it stood out in contrast with the more ephemeral material with which it was flanked, but mainly because it set forth in a convincing manner the invaluable asset which the business man can make of statistical economics. As a result of his study of the business cycle and similar economic subjects, Mr. DENNISON showed how he had stabilized his business with respect to booms and depressions. His company ceased buying raw materials in the winter of 1920, even though orders were piling up and the business boom was at its height. A year later when hundreds of companies were taking a staggering and sometimes fatal inventory loss the Dennison Manufacturing Co. had a clean bill of health.

The incident holds its logical lesson for industry in general, and the chemical and related industries in particular. Consequently the suggestions in this issue by ERNEST T. TRIGG, relative to the possibility of eliminating the very high and very low spots in the business cycle, find an appropriate place in a symposium on increased production efficiency. Can the wavering curve of business be made to approach more nearly a horizontal line? If so, employment would be steadier and

e of the most serious evils of our economic system ould be mitigated. Mr. TRIGG'S suggestion to under- ke construction work, both municipal and private, ring periods of depression is essentially logical. At ch times material and labor costs will be low and the pply plentiful.

The connection between increased production effi- ency and the business cycle is immediate and funda- ental. Nothing is so upsetting to production efficiency irregular production. In a plant working at 100 per nt capacity, the fixed charges—those that do not vary ith rate of production, such as rent, taxes, insurance, preciation, etc.—are a relatively small percentage of e total cost. As production diminishes the ratio of tal cost to fixed charges decreases, and finally a point reached where the total cost exceeds revenue from es. This subject is admirably developed by Professor AUTENSTRAUCH in his article on the budget. The aphical determination of the point is amazingly simple one has accurate costs. And thus we arrive at the ux of the application of economic principles to busi- ss—costs, accurate costs—costs which are not biased any limited point of view, such as sales or produc- on. The development of this theme in its relation to oduction efficiency is covered in this issue by GEORGE COMER, who pleads for a rational interpretation of st data. We look upon his article as excellent am- unition in the campaign which we have consistently aged to impress chemists with the importance and cessity of accurate cost data.

In conclusion, it is well to remember that although oduction efficiency is obviously dependent upon the lution of many technical problems, and although hap- ly the welfare of the worker and other human ele- ents have become recognized factors in efficient oduction, the keystone of success certainly lies in the onomic soundness of a business.

ncreased Production Efficiency From an Engineering Standpoint

PRODUCTION EFFICIENCY can be increased by bringing into play on the elements of production ree kinds of knowledge: engineering science, economic ience, and human relations. The influence of these ree cannot be considered separately, for they overlap many points. However, no one man, be he ever so le, can be thoroughly expert in the application to dustry of more than a small part of any of these anches of knowledge. The knowledge of many, taken gether, must be sought to give us the complete picture.

The engineering phases of increasing production effi- ncy, those phases concerned with the technology of dustry, form an important part of this picture. They al primarily with the proper utilization of buildings d equipment, utilization in such a way as to obtain aximum production for least cost. The important ings to be considered are the design of the plant, e routing and handling of the materials through the ant, the choice and use of the process equipment and e proper application of power to the various opera- ons.

Other factors must be considered which are only in rt of an engineering nature, being fully as much ncerned with economics or human relations. Often ese factors are extremely important from an engineer- g point of view and have a strong influence on the imary engineering problems of production. Among ese perhaps the most important are the lighting, heat- ing and ventilation of the plant; the safety of operating conditions; the standardization of product and operation; and the research work necessary to keep all the foregoing at the best possible level.

In the contributions to this issue will be found much valuable information and many inspiring suggestions as to the engineering means to be employed in increasing production. These contributions are of two types: papers by specialists on the phases of the subject which are their particular concern and short messages from men responsible in the management of different industries. We believe the first category presents an unusual opportunity for the reader to familiarize himself with the basic engineering principles through which the technique of production can be improved, while the second presents the production problems of individual industries and suggests their solution in a manner that cannot fail to be profitable.

The layout of buildings and equipment, the routing of materials through the plant, and the handling of materials in accordance with this routing comprise the most important production problems with which we are now confronted. These three problems must be considered together, and to reach a rational basis of consideration a beginning must be made with the flow-sheet, as A. E. MARSHALL so clearly points out. After the flow-sheet has been established, the routing of the process can be readily determined. This routing forms the starting point for scientific plant design. FRANK D. CHASE shows in his paper on this subject that the important factors in plant engineering are the location, layout, equipment design, finance, operation and management. The bearing of all these factors on the successful operation of a plant should be determined before the plant is built. The material-handling equipment must be chosen on the basis of the routing and the plant layout must fit the exigencies of this equipment. J. G. HATMAN brings before us the fundamental principles on which a chemical plant handling system must be based if its full possibilities are to be realized.

The proper application of power to industry is one of the most important services which the engineer has to perform today. The present tendency is toward the more general use of electricity, and C. B. GIBSON shows us that electric power is power scientifically applied and hence aids the executive in the study of plant problems and leads to more efficient operation, better quality of product and general plant betterment. Steam is the general source of this electric power and in addition has a wide application in the processes of many industries. HERBERT B. REYNOLDS points out in his paper the importance of conserving fuel in the generation of steam power. He feels that generally the power plant is the stepchild of the management, is not understood and for that reason receives much less attention than it profitably should. Power costs should be determined to permit management to know and control this feature of production, realizing thus its best efficiency. Gas is a primary source of heat in many industries and in others is a recognized rival of steam. CARL J. WRIGHT shows how this source of power and heat could be used to advantage more extensively. Gas gives not only increased thermal efficiency but in many cases gives increased quantity and better quality of product.

Among the factors which are not wholly of an engineering nature but which have an important bearing on good engineering in the plant, CHARLES GALLO well points out the advantages to be obtained from good

plant lighting, among which perhaps the most important is that it permits the operators to see clearly and quickly enough to obtain the best results from the equipment. Another means of obtaining the best results from the equipment is brought out in WILLIS H. CARRIER'S thoughtful paper on the value of conditioned air in industry. Safety engineering is generally considered from the point of view of its effect on the personnel, but LOUIS RESNICK'S article on this subject shows that safety of operation also plays an important part in enabling the equipment to function at its best.

Mass production is attained essentially through standardization of product and operation; and for this reason the present active campaign for standardization in industry has a direct bearing on production engineering, for it is by means of mass production that the full advantage of scientific plant engineering is realized. Standardization in chemical industry can be successfully realized only by means of extensive research. C. G. DERICK'S paper on research brings out this fact among many other points of equal importance.

In studying the shorter articles presented by men from the various industries the reader cannot fail to be impressed with the importance of the message which they contain. It avails little to pick out the features of these articles which are of special interest from an engineering point of view. Every reader will profit from a study of this entire symposium. Emphasis may well be given, however, to the point brought out by O. S. SLEEPER, that the road to improvement in process equipment lies through the complete co-operation of chemical manufacturers and equipment makers, and that the progressive manufacturer cannot afford to have any secrets from the man who builds his equipment.

The Eighth Exposition Of Chemical Industries

THE exposition that will open at Grand Central Palace on Sept. 11 will represent the consummation of a year's thought and effort begun when the last one closed a year ago. The orderly arrangement of exhibits will have been assembled for the visitor almost as if by magic, and the carefully planned programs will be carried out with a degree of smoothness and precision that will scarcely be appreciated by those whom they are intended to benefit. Only those who have been directly connected with the preparation of the vast spectacle will have any adequate comprehension of the work involved.

It is doubtful if any technical exposition has grown to the magnitude and enjoyed the degree of popularity that has been attained by the chemical exposition. Essentially technical in its nature, it has nevertheless been able to offer a popular appeal to intelligent people that has undoubtedly done much to create in the mind of the public a sense of the importance of the chemical industry in our national welfare. That it has been possible to increase and sustain this interest for 8 successive years is a tribute not only to the management of the exposition but to the excellence of the exhibits as conceived by those who have made them year after year. They have had a tremendous educational value as well as undoubted commercial and technical importance. Engineers have attended in order to pick up new ideas; college professors have brought their classes for purposes of instruction; and buyers and sellers have even transacted business on the floors of the exposition. All told, it has been a remarkable and ever-increasing success, to which the show for 1922 will be no exception.

Twenty Years of Militant Journalism

WITH the publication of this issue, *Chem. & Met.* rounds out 20 years of growth and service. It was in September, 1902, that *Electrochemical Industry*, as it was then called, was first offered to a friendly but critical group of scientists and industrial leaders who were inaugurating electrochemistry and electrometallurgy in this country. The magazine was conceived in a new spirit of technical literature and born under the favorable auspices of conservative and successful publishing. In the first issue the editor frankly declared an editorial policy "unhampered by precedent" that would enable him to conduct the magazine "along the most advanced lines of modern technical journalism." And "unhampered by precedent" it has been from that day to this.

How well the standards of the founders have been maintained and how nearly they realized their hopes and ambitions are matters of record in twenty-seven volumes of technical literature. That these volumes have been bound and preserved by an unusually large number of subscribers is testimony to a quality of permanence in their value seldom found in current literature. That the journal has reached its present proportions and acknowledged position of importance in the chemical industry is a tribute to its service to reader and advertiser alike.

It is not our purpose here to chronicle the details of 20 years of editorial effort. But a few matters are worth recording. "Unhampered by precedent" the magazine did not hesitate to render service whenever and wherever opportunity offered. This led to growth and expansion. Dr. ROEBER loved to refer to the paper as an insurgent publication, and in September, 1912, on its tenth anniversary he saluted his readers under the caption "Ten Years of an Insurgent Engineering Journal." And the record disclosed a spirit of service and independence that readily accounts for the journal's success and progress. At that time its name had already been twice changed, as its editorial scope and contents were modified to serve an expanding field. And since then equally important changes have been made, all dictated by the demands of the times. Once more the name was changed. Once more "unhampered by precedent" the monthly magazine became an equally successful semi-monthly and finally assumed unquestioned leadership in its field by weekly publication.

Thus we arrive at our present status as an exponent of technology in industry—the application of the principles of science, mathematics and engineering to industrial processes. Once more "unhampered by precedent" we have conceived an editorial scope that covers the broad range of chemical and related industries in which the fundamental processes of chemical engineering are applied. On this basis we serve the ceramist and the soapmaker, the producer of sugar and the manufacturer of paper and pulp, the refiner of petroleum and the burner of lime and cement, the strictly chemical industries and the related manufacture of coal and wood byproducts, fertilizers, paint and varnish, rubber, leather, food and animal products. And hand in hand with this service to technology has developed a fighting spirit of support for the chemical industry in our national life and welfare. The insurgency of a decade ago has begotten the militancy of today. What the future holds we cannot tell, but whatever it be it will still be met "unhampered by precedent."

Program of the Exposition

Four Technical Societies and One Trade Association to Hold Sessions for Reading and Discussion of Papers—Wide Range of Industrial Processes Illustrated by an Excellent Selection of Motion Pictures

ONE of the novel features of the daily technical programs at the Eighth National Exposition of Chemical Industries will be the first session of the recently organized Technical Photographic and Microscopical Society. This organization is made up of technologists in all industries in which photography, microscopy and photomicrography play an important part.

Other organizations that will hold their regular sessions at Grand Central Palace during Exposition Week are the Technical Association of the Pulp and Paper Industry, the American Ceramic Society and the New York Section of the American Chemical Society.

The Synthetic Organic Chemical Manufacturers Association of the United States will hold a session on Tuesday afternoon and there will also be a general meeting at which chemical engineering problems will be discussed.

The motion picture program this year comprises an unusually good selection of films on industrial subjects that will have a strong educational value.

Among the general addresses none will arouse more interest than that scheduled for Monday evening, when Wayne B. Wheeler, counsel for the Anti-Saloon League, will speak on "The Attitude of the Anti-Saloon League Toward Industrial Alcohol."

The detailed program follows:

Program of Speakers and Meetings

All in the Meeting Auditorium—Fourth Floor.

MONDAY, SEPT. 11.

8 p.m.—Opening address by Charles H. Herty, chairman, Exposition Committee.

Wayne B. Wheeler, counsel Anti-Saloon League, "The Attitude of the Anti-Saloon League Toward Industrial Alcohol."

Miss Lida Hafford, director, general headquarters, General Federation of Women's Clubs, "Woman's Interest in Chemistry in America."

TUESDAY, SEPT. 12.

2 p.m.—Meeting of the Synthetic Organic Chemical Manufacturers Association of the U. S.

8 p.m.—E. H. Hale (Liquid Carbonic Co.), "Manufacture, Properties and Application of Carbon Dioxide."

P. W. Heath (Liquid Carbonic Co.), "Using Carbon Dioxide in Ice Cream."

C. R. DeLong (Chemical Division, U. S. Department of Commerce), "How the Department of Commerce Can Serve the Chemical Industry."

WEDNESDAY, SEPT. 13

Pulp and Paper Day

2 p.m.—Meeting, Technical Association of Pulp and Paper Industry, George E. Williamson, chairman.

W. C. Edge (Paul B. Huyette Co.), "Safety and Efficiency Appliances for the Boiler Plant."

E. J. Trimbey (Trimbey Machine Works), "Trimbey and Tibbitts Proportioning and Metering System for Paper Stock."

George L. Dickey (Industrial Filtration Corp.), "Rotary Filters for Washing of Paper Pulp and for Filtering and Washing Caustic Lime Mud." (Illustrated.)

H. A. Morrison (Oliver Continuous Filter Co.), "Efficiencies and Economies in Washing Black Liquor From Digested Soda and Sulphate Stock."

L. D. Mills (The Merrill Co.), "The Merco Nordstrom Plug Valve."

H. S. Thayer (Atlas Electric Devices Co.), "Testing Colored Materials for Fastness to Light."

A. E. Campbell (The Schaeffer & Budenberg Mfg. Co.), "Instruments for Promoting Efficiency in the Paper Mill."

L. G. Bean (The Bristol Co.), "Application of Recording Instruments in Pulp and Paper Industry."

C. C. Phelps (Uehling Instrument Co.), "The CO_2 Record of Combustion Efficiency."

Harry Carlson (Sandvik Steel, Inc.), "Steel Belts and Their Application to the Solution of Conveying Problems."

H. Austin (Ernest Scott & Co.), "Scott Evaporator as Used in the Pulp Mill for Recovering Soda From Spent Liquors."

L. G. Chase (Yarnall-Waring Co.), "The V-Notch Meter and Its Application to the Paper Mill."

W. D. Mount (Glamorgan Pipe & Foundry Co.), "Continuous Causticizing With Lime Recovery and Re-use."

Jerome D. Stein (Grinnell Co.), "The Grinnell Drier Applied to Wall-Paper and Coated Paper."

L. Mann (National Aniline & Chemical Co.), "The Proper Selection and Application of Dyes for Paper."

THURSDAY, SEPT. 14

2 p.m.—Meeting, Technical Photographic and Microscopical Society. (Meeting will take place in Motion Picture Room.) James McDowell, chairman.

Miss Eloise Gerry and Dr. E. M. Diemer (Forest Products Laboratory, Madison, Wis.), "Photomicrography in Pulp and Paper Research Problems."

Henry Green (New Jersey Zinc Co., Palmerton, Pa.), "The Photomicroscopy of Paint and Rubber Pigments."

Dominic S. Mungillo (Craftsmen's Film Laboratory, New York), "How Motion Pictures Are Finished."

Clarence W. Gibbs (Victor Animatograph Co., New York), "Mechanics of Motion Picture Apparatus."

Alfred B. Hitchins, Ph.D. F.C.S. (director Ansco Research Laboratory, Ansco Co., Binghamton, N. Y.), "The Motion Picture as an Aid to Industry."

Guido E. Daub (A. F. Gallun Sons Co., Milwaukee, Wis.), "Microscopy in Leather Tanning."

Albert H. Grimshaw (Textile School, New Bedford, Mass.), "Use of the Microscope in Textile Work."

Philip O. Gravelle (South Orange), "Protozoa and Rotifers: Studies in Microscopic Animal Life." (Illustrated by motion pictures.)

8 p.m.—M. L. Crossley (Colco Chemical Co.), "The Colors That Please Us."

FRIDAY, SEPT. 15

Ceramic Day

2 p.m.—Meeting, American Ceramic Society.

8 p.m.—Meeting, New York Section American Chemical Society. Martin H. Ittner, chairman.

W. D. Collins (U. S. Geological Survey), "Moderation in Standardization."

N. F. Harriman (U. S. Bureau of Standards), "Standardization From the Consumer's Point of View."

I. G. Jennings (Glass Container Association), "Discussion of the Reasons for the Varieties of Shapes and Sizes."

J. M. Roberts (secretary of the Apparatus Manufacturers' Association of the United States), "What Has Been Accomplished in the Standardization of Scientific Apparatus."

Ross C. Purdy (secretary, American Ceramic Society and chairman of committee on refractories of the American Society of Testing Materials), "Standardization of Fireclays and Refractories."

Emerson C. Poste (Elyria Enameled Products Co.), "Standardization of Enameled Wares for Chemical Purposes."

William A. Durgin (Division of Simplified Practice, Department of Commerce), "Standardization."

Motion Picture Program

All in the Motion Picture Room, Fourth Floor

TUESDAY, SEPT. 12

2 p.m.—"The Story of Sulphur" (2 reels), Courtesy, U. S. Bureau of Mines and Texas Gulf Sulphur Co.

"Dust Explosions" (1 reel), Courtesy, U. S. Bureau of Chemistry.

"Protecting Buildings Against Lightning" (1 reel), Courtesy, Baltimore Copper Works.

"The Story of Asbestos" (4 reels), Courtesy, Johns-Manville Co.

"Nickel and Copper Mining, Smelting and Refining" (3 reels), Courtesy, International Nickel Co. (Speaker.)

"Recovering Values From Fume and Smoke" (1 reel), Courtesy, U. S. Bureau of Mines and Research Corporation.

7:30 p.m.—"The Story of Natural Gas" (4 reels), Courtesy, U. S. Bureau of Mines.

"Extinguishing the Largest Oil Fire in the History of Casper, Wyo." (1 reel), Courtesy, Foamite-Childs Corporation.

"The Romance of Cotton" (1 reel), illustrated with address by David Wesson of Southern Cotton Oil Co.

"The Story of Air Reduction" (4 reels), Courtesy, U. S. Bureau of Mines.

WEDNESDAY, SEPT. 13

2 p.m.—"The Story of Heavy Excavating Machinery" (4 reels), Courtesy, U. S. Bureau of Mines.

"The Story of Abrasives" (4 reels), Courtesy, U. S. Bureau of Mines and the Carborundum Co.

"Prospecting for Gold in Northern Ontario," and "Assaying for Gold in Northern Ontario," (3 reels), Courtesy, Ontario Department of Mines.

7:30 p.m.—"The Manufacture of Newsprint Paper at the Spanish River Pulp & Paper Co. Mills in Ontario" (8 reels), Courtesy, The G. H. Mead Co.

"Barrel Making in America" (2 reels), Courtesy, Lucas E. Moore Stave Co.

"The All-weather Fire Extinguisher That Won't Freeze" and "An Industrial Firefoam Sprinkler System" (1 reel), Courtesy, Foamite-Childs Corporations.

THURSDAY, SEPT. 14

2 p.m.—Room occupied by meeting of T.A.P.P.I.

7:30 p.m.—"Mexican Petroleum" (4 reels), Courtesy, U. S. Bureau of Mines.

"Extinguishing the Largest Oil Fire in the History of Casper, Wyo." (1 reel), "Fire-Extinguishing Tests on Blazing Oil Tanks at Port Arthur, Tex. (1 reel), Courtesy, Foamite-Childs Corporation.

"Protozoa and Rotifers: Studies in Microscopic Animal Life" (1 reel).

"Inspiration: One of the World's Great Copper Mines" (3 reels), Courtesy, U. S. Bureau of Mines.

"How Motion Pictures Are Finished" (1 reel), Courtesy, Craftsman Films, Inc.

FRIDAY, SEPT. 15

2 p.m.—"Prospecting for Gold in Northern Ontario" and "Assaying for Gold in Northern Ontario" (3 reels), Courtesy, Ontario Department of Mines.

"Inspiration: One of the World's Great Copper Mines" (3 reels), Courtesy, U. S. Bureau of Mines.

"Nickel and Copper Mining, Smelting and Refining" (3 reels), Courtesy, International Nickel Co. (Speaker.)

"Protecting Buildings Against Lightning" (1 reel), Courtesy, Baltimore Copper Works.

"An Industrial Firefoam Sprinkler System" (1 reel), Courtesy, Foamite-Childs Corporation.

7:30 p.m.—"The Story of Natural Gas" (4 reels), Courtesy, U. S. Bureau of Mines.

"The Story of Abrasives" (4 reels), Courtesy, U. S. Bureal of Mines and the Carborundum Co.

"Barrel Making in America" (2 reels), Courtesy, Lucas E. Moore Stave Co.

"Dust Explosions" (1 reel), Courtesy, U. S. Bureau of Chemistry.

SATURDAY, SEPT. 16

2 p.m.—"The Story of Air Reduction" (4 reels), Courtesy, U. S. Bureau of Mines.

"The Story of Asbestos" (4 reels), Courtesy, Johns-Manville Co.

Classified List of Exhibitors

A List for Ready Reference From Which the Busy Reader Can Quickly Ascertain the Names of Those Companies Exhibiting the Special Products in Which He Is Most Interested

IN AN EFFORT to render better service both to the readers of *Chem. & Met.* and the exhibitors at the exposition, a new method of presentation has been adopted this year. Hitherto we have given an alphabetical list of exhibitors with a brief explanatory statement of their exhibits. This has not been wholly satisfactory, because readers were more interested in the material exhibited than in the concerns exhibiting.

Accordingly this year we have classified the exhibitors according to the character of their exhibits and have listed the companies under classifications that will enable the reader to see at a glance who is exhibiting the things in which he is most interested.

No attempt has been made to give the booth number of the various exhibitors, as this will be more conveniently ascertained by reference to the pocket-size program that we shall distribute at the exposition. The principal purpose of the present classification is to enable the reader to determine at leisure those things to which he will prefer to devote the most of his time.

Abrasives:
The Carborundum Co.
Norton Co.

Absorption Equipment:
Silica Gel Corp.

Acid Plants and Equipment:
United Lead Co.

Acid-Resisting Materials:
Bethlehem Foundry & Machine Co.
The Duriron Co., Inc.
Electro-Chemical Supply & Engineering Co.
General Ceramics Co.
General Filtration Co., Inc.
Haynes Stellite Co.
Maurice A. Knight
Luzerne Rubber Co.
Johns-Manville, Inc.
J. L. Mott Iron Works
Nitrose Co.
Westinghouse Elec. & Mfg. Co.

Agitators:
Bethlehem Foundry & Machine Co.
The Dorr Co.
General Ceramics Co.
Hunter Dry Kiln Co.
F. J. Stokes Machine Co.
The Carrier Engineering Co.
W. L. Fleisher & Co., Inc.

Alcohol:
Alcohol Warehouse Corp.
U. S. Industrial Alcohol Co.

Alloys:
American Brass Co.
American Manganese Bronze Co.
Anaconda Copper Mining Co.
Anaconda Rolling Mill Dept.
Aterite Co., Inc.
Baker & Co., Inc.
British-America Nickel Corp., Ltd.
Calorizing Co. of Pittsburgh
The Duriron Co., Inc.
Haynes Stellite Co.
Hoyt Metal Co.
International Nickel Co.
International Smelting Co.
Monel Metal Products Co.
Tuc-Tur Metal Corp.
United Metals Selling Co.
York Metal & Alloys Co.

Asbestos:
Johns-Manville, Inc.
Powhattan Mining Co.

Asphalt:
The Barber Asphalt Co.

Associations:
National Lime Association
Talc & Soapstone Producers Assn.

Autoclaves:
M. W. Kellogg Co.

Automatic Machinery:
Economic Machinery Co.
Edward Ermold Co.
Karl Kiefer Machine Co.
Mohan & Co., Inc.
Standard Sealing Equipment Corp.
Trimbey Machine Works
Wallace & Tiernan Co., Inc.

Bags:
Arkell Safety Bag Co.

Balances:
Christian Becker, Inc.
Palo Co.
Voland & Sons

Bakelite:
The Bakelite Corp.
The General Bakelite Co.

Barrels and Drums:
The Associated Cooperage Industries of America
Chess & Wymond
The Cleveland Cooperage Co.
B. & A. D. Fessenden Co.
Pioneer Cooperage Co.
Pressed Steel Tank Co.
Seymour & Peck Co.

Belting:
R. & J. Dick Co., Inc.

Blowers and Fans:
Abbé Engineering Co.
Beach-Russ Co.
The Duriron Co., Inc.
General Ceramics Co.
Schutte & Koerting Co.
B. F. Sturtevant Co.

Books, Technical:
P. Blakiston's Son & Co.
J. B. Lippincott Co.
D. Van Nostrand Co.
John Wiley & Sons, Inc.
H. W. Wilson Co.

Burners:
Glens Falls Machine Works
Macleod Co.
Surface Combustion Co.
Trimbey Machine Works
Will Corp.

Canada:
Dominion Water Power Branch
Forest Products Labs. of Canada
Ontario Dept. of Mines

Carbon Products:
Barnebey Cheney Engrg. Co.
Carbrox Co., Inc.
Darco Sales Corp.
Industrial Chemical Co.

Centrifugals:
De Laval Separator Co.
Fletcher Works
Sharples Specialty Co., Inc.
Tolhurst Machine Works

Chemical Engineers:
H. F. Jacoby
Petri & Dorr

Chemical Plant Equipment:
Allis-Chalmers Mfg. Co., Inc.
A. J. Becker
Benzine Condensation Co.
Buffalo Foundry & Machine Co.
Builders Iron Foundry
Clipper Belt Lacer Co.
Corning Glass Works
Crane Co.
Crane Packing Co.
J. P. Devine Co.
Electro Bleaching Gas Co.
The Elyria Enameled Products Co.
Filtration Engineers, Inc.
General Ceramics Co.
Glamorgan Pipe & Foundry Co.
Glens Falls Machine Works
Haynes Stellite Co.
International Nickel Co.
Henry E. Jacoby
Janney, Steinmetz & Co.
M. W. Kellogg Co.
Maurice A. Knight
L. O. Koven & Brother
La Bour Co.
Monel Metal Products Co.
J. L. Mott Iron Works
Niagara Alkali Co.

Labor's Responsibility for Industrial Efficiency

By James J. Davis
Secretary of Labor

THE word efficiency has come to be looked upon as somewhat of a fetish in our modern industrial life. To many of us it conjures up bespectacled experts, armed with vast documents and charts, who speak of plats, and peaks, and depressions, and index numbers and curves.

Photo copyright by Harris & Ewing.

James J. Davis
Secretary of Labor

But experts are as experts do. Many times we need them sorely. Sometimes, however, I am inclined to throw up my hands and say, "Let us have a little less efficiency and a little more common sense."

For when we embark on the wide sea of mathematical formulas and seek to index the power of every human cog in the industrial machine, there are too many opportunities for us to overlook some vital factor in our calculations. We are likely to think a little too much in terms of figures, and a little too little in terms of manhood. For behind all of the calculated niceties of mathematically charted efficiency lies the human factor, and no mathematician since Euclid has yet been able to reduce humankind to exact arithmetic. After you have reduced every industrial operation to formulas, you have behind them always the algebraic unknown quantity, *x*, humankind.

Ultimately, efficiency in industry today rests with labor. The American workman bears upon his shoulders a heavy responsibility to himself, his craft, his industry and his country. For upon him depends, in large measure, the quantity and quality of the nation's production of marketable goods, the index and basis of

prosperity for the individual, the community, the industry and the country. In the work that lies before the hands of the workman is day by day the fate of himself, his employer and the great consuming public that waits on his products. If he falters, no matter what the cause, the result is felt by all dependent on his labor.

More and more, labor in America is coming to realize the tremendous responsibility which rests upon it and the certainty with which it faces disaster unless it accepts and discharges that responsibility. Just as the modern employer has come to realize that he must pay his labor a wage that is more than merely enough to provide him with food, clothing and shelter, the workman is facing his duty to himself and society. The employer who is abreast of the times knows that his workers, and the workers of every other employer, must receive not only a living wage but a saving and buying wage. He knows that the 40,000,000 gainfully employed in America provide out of their wage surplus the vast buying power of America upon which all industry is dependent and without which there can be no prosperity in the land. The workman is learning that to earn a saving wage he must deliver an honest day's work in order that the industry which supports him and his may endure and prosper.

THERE can be no excuse for the worker who shirks on the job, who fails to give to his employer the honest best that is in him. The laboring man who accepts his wage and deliberately slows down his efforts is no better than the bandit who with revolver and jimmy enters the employer's office at midnight and loots the safe. He is taking what does not belong to him. He is doing injustice to himself, his employer and his fellow workers. He is jeopardizing the prosperity of every individual who is touched by his work. I am inclined to think there are few of this type of worker in American industry. I am convinced there are not many who have the point of view of the workman who was approached by an exasperated foreman with the reprimand:

"Here, John, what's the matter? Don't you see that the man beside you is doing three times as much work as you are?"

"I know," was the reply, "I've spoken to him about it half a dozen times, but he doesn't pay any attention to me."

THE greatest need in America is industrial peace. Without it we cannot have our highest production, and without our highest production we cannot bring the nation to its highest prosperity. Industrial warfare, with its constant interruption of production, is the greatest enemy to efficiency in production. To end industrial warfare we need understanding and co-operation between the men who manage industry and the men whose labor makes industry possible. The highest efficiency is reached by that industry in which the employer knows intimately the problems and needs and aspirations of the workers and in which the worker has a sympathetic understanding of the difficulties and discouragements and purposes of the employer. Many of our present-day industrial difficulties were unknown in the days when industry, organized on a much smaller scale, permitted closer personal relations between the men who managed industry and the men who worked in it. The successful surmounting of these difficulties lies in developing some system whereby that close personal relationship may be restored or some adequate substitute found for it.

WE HEAR much talk of man's inhumanity to man in industry, but every man in his personal relationship is essentially human. Inhumanity, in the majority of cases, arises from ignorance.

Efficiency in industry, then, turns largely on the human factor. The human relationships in industry call for a more intimate knowledge among employers of their workers and their problems and for a wider appreciation among workers of the difficulties and aims of their employers. With a closer relationship between employer and employee, a wider knowledge of the problems confronting each, we may look toward the inauguration of a real Golden Rule in industry, that will bring efficiency to its highest point.

Washington, D. C.

Increased Production Efficiency Means Good Material Handling

The Material-Handling Problem in the Chemical Plant—Analysis of This Problem and Some Suggestions Toward Its Solution—Advantages Derived From Good Material-Handling Methods

By J. G. Hatman
Material-Handling Section, American Society Mechanical Engineers
Production Engineer, Frankford (Pa.) Plant, The Barrett Co.

THE majority of chemical plants in the United States are additions to existing industries. During and just prior to the war our national chemical industry knew an enormous expansion. In the rush of this building program conditions were more or less chaotic. Production at any cost was the absolute need of the times; and there was no opportunity, and little inclination, to consider the means by which this production could be attained in an efficient and economical manner.

Other plants besides these war plants existed, but they had been built in days of little competition and there had been no incentive for their owners to adopt the most efficient means and machinery of production. For this reason we find practically all chemical plants today in serious need of effecting reductions in their production costs, for on these reductions depends their ability to meet the keen competition of crowded market and low demand—depends, in fact, their continued existence.

Means by Which Costs May Be Reduced

The three essential elements of a manufacturing concern are buildings, equipment and personnel. When we have the best possible in each of these three divisions —properly co-ordinated by a sane and efficient management—we have the ideal in organization and, *per se*, the lowest possible production costs.

Perhaps perfection in any one of these three elements, or in the management that controls them, is unobtainable; but the approach to perfection is open to all, and it remains only to study these various elements and determine in what way the approach shall be made. Elsewhere in this issue the subjects of buildings, personnel and management are treated. Here the attempt will be made to point out what seems to the writer the most important way in which equipment can be treated with a view to lowering costs and increasing efficiency.

The Equipment Problem in the Chemical Plant

Modern manufacturing equipment consists of two main divisions: equipment which performs the various operations in the manufacture, and equipment which serves to bring the material to and take it away from machines of this first division. These two classes may be called—in their simplest terms—process equipment and material-handling equipment.

The equipment problem is, therefore, twofold. It is necessary to have the best possible process equipment, adapted to the particular circumstances of the given plant, that may be procured. It is necessary to have such material-handling equipment as will enable all the other elements involved—the buildings, the process equipment, the personnel and the management—to realize each its best performance.

The Status of Process Equipment

Process equipment is a matter of development. At any given time the manufacturer has available for his use equipment which represents the best results of research and invention in his particular line. In some instances it may, in the light of information in the manufacturer's hands, be possible to make improvements in this equipment which will render it more efficient and thus lower production costs. Also, the function of management, in housing, arranging and controlling the operation of the equipment, can do much to render it efficient.

The great means, however, for improving the efficiency of industry through the process equipment lies in the development of improvements through research and invention. This is a matter of time. Constantly new items appear. The alert manufacturer, who keeps his eye on the market and adopts the best of this equipment suited to his needs and applies it in the most efficient manner, is doing the best that can be done toward realizing on the process equipment itself.

The Status of Material-Handling Equipment

The material-handling equipment, however, presents an entirely different range of possibilities to the management which seeks to reduce costs. Here we have an almost infinite variety of appliances—well designed and thoroughly tested. While improvements will no doubt occur from time to time, there is no point in waiting. The equipment available is good enough, efficient enough, for present needs; and the problem of the management is to select the proper equipment and then proceed to realize the maximum of benefit from its use.

Handling Problem in Chemical Industry

Handling, in chemical industry as in any other field, divides readily into three divisions. These are: Inbound—crudes and intermediates; interdepartmental—between processes; and outbound—finished products. The problem of the design or choice of the handling equipment is likewise concerned with three major requirements as follows:

1. To have the bulk raw materials available at the time, in the place and in the quantity desired.
2. So to move the materials from department to department, from process to process, that each piece of process equipment is kept working at its most efficient rate.
3. To remove the finished products from the productive departments in such a way that production is not blocked. To take them into and out of storage in the most economical manner. And to provide for expeditious and efficient shipping.

The Raw Material Problem

In general, all crudes should be received at one point unless the particular crude is used in only one department. In this case it may be more conveniently unloaded at that place.

The raw materials, be they crudes or intermediates, will generally be received in one of the following ways:

1. Liquids in tank cars or tank ships.

2. Bulk dry materials in cars or ships.
3. Bags in cars, motor trucks or ships.
4. Barrels in cars, motor trucks or ships.
5. Drums of solids or liquids in cars or ships.

Raw Materials in Liquid Form

The bulk raw materials received in liquid form in tank cars or tank ships may be efficiently handled in two ways—i.e., they may be pumped or they may be blown by compressed air.

In case the handling is done by pump, care must be taken that the pumps and pipe-lines are large enough to assure the desired end of unloading maximum gallonage in the minimum time.

In many branches of chemical industry the use of compressed air for blowing liquid material from tank cars or tank ships should be employed with caution, if at all, as there is some danger involved in this method with certain materials. In case this method is the suitable one to use, care should be taken to have a sufficient supply of compressed air, of a proper pressure, available when needed.

In either of the above cases, the pipe-lines used are worthy of careful study. These pipe-lines should follow the straightest course which can be obtained. They should have no traps or sharp bends. Fittings should be used as sparingly as possible. In the case of liquids which crystallize or become viscous at ordinary winter temperatures, the pipe-line should be protected from the weather and suitably heated. In any case, means should be provided for steaming out and blowing out the lines.

Bulk Dry Materials

Bulk dry materials may be received in gondolas or boxcars; in cargo ships; or, in rare cases, in motor trucks. In any case, these materials will be stored in some type of bin or in a storage pile.

Unloading will be best taken care of by dumping into a track pit from the gondolas. Trucks and boxcars should be unloaded into a pit also. For the boxcars, there are several types of efficient unloaders to be obtained, including the mechanical shovel and the portable belt unloader. This class of material is generally unloaded from a ship's hold by some type of crane, depending on such conditions as the size of the ship and the disposal of the material.

Handling this class of materials from the unloading point to storage and to process may be done by various types of handling equipment such as cranes, belt and bucket conveyors, storage battery trucks, industrial railways. The choice depends, among other things, on the amount and nature of the material to be handled and the physical conditions in the plant. Each case of this type calls for a careful study and the exercise of sound judgment in making a choice. It should always be borne in mind that the main consideration is properly to feed the process equipment—to have the right amount of material at the desired place when it is wanted.

Handling Bags, Barrels and Drums

Bags, barrels and drums should be unloaded on one central platform. This platform should be at car-floor height and can be so arranged as to serve trucks in cases where the material is so received. Where ships are used to bring this type of material to the plant, special arrangements must be made to accommodate the unloading. A scale should be placed near the unloading point so that materials can be weighed without rehandling.

This class of material can best be stored in a central storehouse. The quantities are taken from stores only as desired—a reserve can be maintained—and the feeding of the process equipment in the cheapest and most efficient manner can be more readily arranged.

Handling of materials in these containers from the car, truck or ship to the storehouse and from the storehouse to the manufacturing departments is generally best accomplished in chemical plants by some form of mobile transportation. Monorails and various types of conveyors are efficient in special cases; but small motor trucks or tractors drawing several trailers generally accomplish best the results desired.

Arrangements should be made for the economical removal of the material from the bags, barrels and drums and its movement to the start of the process in which it is used. This emptying should be done as near the place of usage as possible. Drums of liquid can be emptied conveniently by rolling them onto a track under which is a pan to be emptied by hand or a catchbasin which may be pumped out. Several drums can be emptied at once in this manner. Barrels and bags can be dumped over a grating and a drag conveyor used to get the solid material to the apparatus where it is to be used.

The Interdepartmental Problem

Material handling between departments and processes of a chemical plant depends primarily on two things: the nature of the material to be handled and the type of process equipment between which the handling is to be done. As a secondary but sometimes strongly influencing consideration there is the consideration of position, the relative elevations of the two points, the distance between them and the intervening topography.

Governing conditions will vary greatly in this phase of handling. For this reason it is possible to give only general recommendations. For handling liquids the general run of operations will be best served by gravity flow in pipe-lines where the elevation lowers and by pumping where the elevation increases. Because processes or departments of chemical plants are most often housed in separate buildings, the only general recommendation that can be made is that the solid materials should be placed in some type of container and transported by truck or tractor and trailers. There are many special cases where other types of handling equipment are the most economical; but the tractor or truck method is of almost universal application here.

The Pacemaker of Production

Most careful attention should be given to the selection and operation of the interprocess handling equipment. As stated above, this equipment must so move the material that each item of process equipment is kept working at its most efficient rate. For this reason we can call this part of the handling equipment the pacemaker of production. The output of the productive departments depends entirely upon the way in which the materials are moved through them. The workers must keep the pace of the machinery.

As a method of procedure in solving a problem in interprocess handling, there should first be determined the most rapid rate at which the process equipment can turn out the desired quality of product. The han-

dling equipment should then be chosen, designed and operated to feed the process equipment at exactly this rate. Given such conditions, it becomes the duty of management to provide the personnel to realize the best results. This problem is much simpler than the problem of obtaining efficient production where no handling system, or a poor one, exists.

The Finished Product Problem

The finished products can be classified in two different ways. First, as liquids and solids. Second, as materials to be shipped in bulk and materials to be shipped in small quantities.

The elements of the problem involved in handling these products comprise getting the material from the end of the process to the place where it is put in the container; placing it in the container; taking the container to the finished-goods storehouse; and moving the finished goods from this storehouse to the car, truck or ship in which they are to leave the plant.

Bulk Liquid Products

Bulk liquids will generally be shipped in tank cars or tank ships. The most efficient system is to move these by gravity through pipe-lines. This method is the cheapest and prevents any possibility of contamination. Where gravity cannot be used, resort should be had to pumps. The same general considerations on pipe-lines that obtain with liquid raw materials apply to liquid finished products.

It is very seldom compatible with the best efficiency to have the daily production correspond exactly with the daily shipments. For this reason tank storage should be provided for the liquid finished products. The size and location of these tanks should be carefully determined with the plant requirements and conditions fully in view.

Bulk Solid Products

Almost invariably, bulk solids should be shipped in some kind of container and not loose. The loss from waste, spoilage and contamination in loose shipments makes the container a saving rather than an expense. But this container should be the cheapest one which will give efficient service.

These bulk solids are usually in crushed or powdered form. If they are not, the case is too unusual to be considered in the scope of this paper. Some of these products are chemically active and require highly specialized containers. The general run of material of this type can, however, be handled in bags, barrels or drums. Of these three containers the bag is the best and most economical for the following reasons:

1. The cost of the bag is lowest.
2. A larger net quantity of product can be shipped per car.
3. Less space is required to store the empty containers.
4. Automatic bagging equipment is available.
5. Less labor is required for closing.
6. Bags are handled more simply than other containers.

Handling for Bulk Solid Products

If we consider only the general case of bulk solid products in crushed or powdered form to be packed in bags, an extremely simple and efficient handling routine can be established. The material can be moved from the last manufacturing process to the bag-filling equipment by a belt conveyor and automatically fed to the filling machine. The filled and closed bags from this machine should be deposited on skids and these skids taken to the storage space by lift truck.

During storage the bags should remain on the skids. In this way any rehandling is saved—for when the material is to be shipped the skidful of bags can be taken on the lift truck again and moved to the shipping point without touching the bags. One man can handle as many bags per day in this way as six could handle were a system to be used where rehandling were necessary.

In loading truck, car or ship the lift truck can run directly to the point at which it is desired to place the bags. In loading the hold of a ship, the bags have to be stacked too high for the work to be economically done by hand. About one-half the loading crew can be dispensed with if a motor-driven stacking machine is used and a very definite saving is thus effected.

Materials Shipped in Small Quantity Units

A large part of the product of chemical industry must be shipped to the consumer in small unit quantities. Although the total shipped by a plant to any given primary consumer may be large, such large quantity will consist of many small packages. The elements of the handling problem are here the same as in the case of bagged materials.

These materials will occur in various forms—liquid and solid. The difficulty of the problem lies in the fact that one plant may produce a large variety of such substances. As a result, various means of filling the containers must be employed and after filling will come the problem of handling to storage and shipping a collection of packages which often will fit no one system of conveying.

Handling for Miscellaneous Containers

It is in the solution of this difficulty that we find room for the greatest improvements. The finished materials, after leaving the manufacturing processes, can be moved to the filling department, if liquid by gravity or pump, and if solid on a belt conveyor. After the containers are filled they may be taken to storage and shipment in a variety of ways. There is conveying equipment available to solve any problem of this nature and the point is to select that equipment which will move the material most efficiently and with the fewest number of men. It is also important to keep the flow of finished product away from the manufacturing departments as steady as possible, so that there will be no tendency for the material to accumulate and clog production.

A successful solution of this problem from the experience of one of the largest plants in the country shows what can be done along these lines. The nature of their products made necessary a large variety of containers of different weights and sizes. Finding the hand method of movement too costly, they had a thorough study made of the possibilities of their case. As a result, they adopted a special type of skid having a boxlike receptacle mounted on it, the walls of which could be varied in height. They then standardized on containers—still various in size and shape—which would fit into these receptacles.

A multiplicity of these skids were built. Lift trucks handled the skids at the plant and into cars and ships.

Goods were shipped to their branches in the receptacle-skids and at those points lift trucks again did the moving. The saving effected was nine-tenths of the sum previously spent on handling.

Importance of Containers

The possibility of finding any means of successfully handling these small and varied products largely lies in the simplification and standardization of containers. There is no reasonable excuse from a manufacturing or business standpoint for the great variety of those now in use. The successful manufacturer will concentrate all his effort on supplying products packed in a few standard sizes and shapes. This will cut down the costs for storage of empty and filled containers. It will greatly reduce the time and labor necessary for filling. And it will render possible the adoption of an efficient handling system—one that will effect further savings in time and labor—one that will aid in attaining an efficient functioning of the plant as a whole.

How Good Material Handling Aids Production Efficiency

The elements of the handling problem in chemical industry and methods to be used in seeking its solution have been brought out in as much detail as is possible in a short article. Now let us consider how the solution of this problem will affect production.

It was stated above that production could be improved by bringing buildings, equipment, personnel and management to a higher level. The rôle of the handling equipment is that of the efficient servant—a servant which functions to permit its four masters to realize their best possibilities and without which they are unable to operate in harmony. Let us note some of the ways in which this servant can help its masters toward higher efficiency.

Relation of the Handling System to the Buildings

The effect of a well-designed, efficient material-handling system on the utility of the buildings is threefold:

1. It allows for a fuller utilization of the manufacturing space by doing away with the necessity for storage spaces between processes and permitting the process equipment to be placed in the most economical manner.

2. It lessens the amount of space which must be devoted to storage of raw materials, because it feeds the process more efficiently.

3. It lessens the amount of space which must be devoted to storage of finished products, because it enables the management to count on a continuous production of definite dimensions and to plan distribution accordingly.

Relation of the Handling System to the Process Equipment

The well-designed, efficient material-handling system aids the process equipment to function in the following ways, among others:

1. It feeds the material to the machine continuously at the exact rate at which the machine operates most efficiently.

2. It removes the material from the machine continuously at the exact rate at which the product is finished.

3. It prevents the accumulation of finished or unfinished goods about the machine, which reduces the space overhead chargeable to it and allows complete freedom of operation.

4. It greatly reduces the amount of labor expended on the process—both direct labor and indirect labor; allows the process equipment to function in as nearly an automatic manner as possible and thus permits the process equipment to produce its maximum at the lowest possible cost.

Relation of the Handling System to the Personnel

Some of the effects of a well-designed, efficient material-handling system on the personnel of the manufacturing plant are:

1. It reduces the personnel to the lowest possible number.

2. It permits the employment of only the skilled or semi-skilled class of workers.

3. It enables the employee—provided the other elements of building, process equipment and management are efficient—to work at his best and hence command a high rate of pay.

4. It takes the burden of physical labor from the laborer and makes him a brain worker.

5. Through the four gains stated above, it helps to achieve the maximum of production per dollar of payroll and hence increases the production efficiency.

Relation of the Handling System to the Management

Good material handling is the mechanical substitute for management:

1. By relieving management of a vast burden of detail, it permits management to function in a broader way, to maintain a better control of the elements of production and more successfully to anticipate fluctuations in productive demand.

2. We have called mechanical handling the pacemaker of production. It gives the management much more dependable production figures than could be had with manual methods. It holds the worker—easily and without overstrain—to a definite and high productive pace—and this with little effort along the lines of supervision.

3. Clerical, administration, insurance and other overhead costs are greatly reduced. This follows naturally on the lessening of the labor force and the greater ease of obtaining cost figures and other data which management needs.

Relation of Material Handling to Productive Efficiency of Manufacture

Material handling knits manufacture into one whole and permits management to treat it more and more as a unit, as a machine, to which material is fed and from which finished goods are received. This trend, carried to its ideal end of perfectly effective manufacturing elements—buildings, process equipment and personnel—co-ordinated in effort by a perfectly adapted automatic handling system, would result in the practical elimination of all management and the realization of the minimum production costs. This is the goal—one which can never be reached, but toward which the mechanical handling system is rapidly carrying those who are far-sighted enough to take advantage of its possibilities.

Frankford, Pa.

Wages

The Fundamental Relations Between Employer and Employee Upon Which Wage Payments Are Based—Essentials of a Good Wage System —How Wages Should Be Measured—How These Theories Work Out in Practice Illustrated by the Results Obtained in the Ford Industries

By Harrington Emerson
President, The Emerson Engineers

I WAS brought up on the Bible, my father being a clergyman, and I still turn to it for instruction. What I like about the Bible is that it gives us principles rather than expedients.

As I read the texts, these principles seem to be, that the relation of employer and employee is very exalted, comparable to the Kingdom of Heaven; that wages rest on free contract and agreement; that standard wages are by the day and payable daily; that the factory is the employer's own and he has the sole right to judge of his needs; that he can freely select those who are better than others and that he can pay these better men a higher wage, but not pay a lesser wage than the standard to any employee, however incompetent, and that wages shall not be oppressively low.

Fundamental Relations

"For the Kingdom of Heaven is like unto a householder which went out early in the morning to hire laborers into *his* vineyard, and when he had agreed with the laborers for so much a day [not by the hour or piece] he sent them into *his* vineyard." And he hired other laborers later and said unto them: "Go also into the vineyard and whatsoever is right, that shall ye receive."

And at the day's end he paid none less than he had agreed and that they had voluntarily accepted; and he paid some more than they expected, and some expected more than they had agreed for and they murmured; but the householder answered one of them and said, "Friend, I do thee no wrong. Didst thou not agree with me? Take what is thine and go thy way. Is it not lawful for me to do what I will with my own? The last shall be first and the first last, for many are called but few are chosen."

The Bible is very severe against delays or holding back of wages or arbitrary reductions.

"The wages of him that is hired shall not abide with thee all night until the morning."

"Behold the hire of the laborers who have reaped down your fields, which is of you kept back by fraud, crieth."

"I shall be a swift witness against those that oppress the hireling in his wages."

"Your father hath deceived me and changed my wages ten times."

And this for the wage earner: "Do violence to no man, neither accuse any falsely, and be content with your wages."

I knew a modern enterprise with three thousand employees that paid them all off daily.

Evolution of Employer-Employee Relations

A further fundamental fact about the relations of employer and employee is that the evolution is from status to contract. There was a time when workers were slaves, working like horses, without wages; but for food, shelter and clothes. Then came serfs, part of whose time was their own, but they could not leave the land; then came the "corvée," forced labor without compensation. The worker had to do the master's work first. We are slowly, oh, so slowly, progressing into full contract; but many harmful restrictions still linger on. Man is an animal, very slow to observe and adopt improvements. Five hundred thousand years ago he observed insects and birds flying all about him, but until this generation it never entered his head to try even to glide. So also in the matter of wages, we have not nearly reached full contract.

Because conditions have improved in the last hundred years and because labor unions have agitated for better conditions, for the abolition of abuses, it is, without reliable foundation, claimed by some that trade unions deserve the credit for the changes; and that without trade unions there would have been no progress. This is an untenable conclusion.

Development of Contract Relations

In earlier centuries the Church inveighed against the practice of keeping Christians in bondage and practiced manumission.

The anti-slavery agitation of the last century was due to the advancing spirit of humanity preached by the reformers of the eighteenth century in France, which worked out into the French Revolution, with its slogan of "Liberty, Equality, Fraternity."

In England a form of slavery existed down to the end of the eighteenth century. Colliers and salters, on entering into a coal work or salt mine, were bound by the law, independent of bargain or agreement, to perpetual service; and in case of sale of the ground, their services passed with the title. The sons of the collier and of the salter could follow no occupation but that of their father and were not at liberty to seek employment elsewhere than in the mines to which their fathers belonged.

It was decided in 1772 that no slaves could be imported into England. In 1787 a society was formed in London to suppress the slave trade. Wilberforce and Pitt agitated in Parliament. Slave trading was made illegal after Jan. 1, 1808, and in 1811 it was made a felony; in 1824 it was made piracy. The French freed their negroes in 1848, the Dutch in 1863. In the United States slavery was curtailed, not through the efforts of the slaves or of labor unions, but through the opinions of enlightened individuals as Franklin, Washington, Hamilton, Jefferson. The Pennsylvania Abolition Society was formed in 1775. William Lloyd Garrison, Wendell Phillips, Arthur Tappan were active in 1831. The Free Soil party was formed in 1848. Slavery was ultimately abolished in the United States, Jan. 1, 1863.

The modern theory of work is that the better the worker the lower the labor cost. The modern theory is

hat the worker is a supervisor, but tools and machines o the heavy work. These theories have been enunciated and put into effect by enlightened and progressive mployers in advance of and beyond any claims of trade nions. The Cadburys in England, also Lord Leverulme; in the United States, above all others, Henry ord and the American Rolling Mill Co. have led the ay.

Essentials of a Wage System

It is easy to enumerate the essentials of a good wage ystem.

(1) Free agreement between employer and employee s to the basic daily wage for the locality and occupaion.

(2) Definite understanding as to the amount of outut, whether through direct work or supervision, or oth, that is to be given as an equivalent of the wages. This is often wholly ignored by both parties to the ontract. It is exceedingly rare to find any agreed to quivalents, much less fair equivalents.)

(3) An understanding that any deviation by the mployee in the way of delivering more than the conract wage equivalent shall be fully recognized and paid or by the employer.

These essentials are embodied in the wage agreenents with trainmen.

The wage is so much per day of 8 hours. An agreedo number of miles is a day's work. More miles within hours, or more than 8 hours, receive extra comensation.

An Additional Principle

A fourth principle is looming up—namely, that the horter the day the higher should be the pay per hour; he longer the day the lower the pay per hour. This rinciple is based on the fact that a supervisory or anual or mental worker can deliver more per unit of ime for a few hours than during many hours. A printer can run 100 yards at the rate of 20 miles an our, but for 2 hours the rate of speed drops to 10 iles an hour. A man can fight but a few prizefights n his lifetime; he can do less strenuous work conuously for 60 years.

The time is coming when the shift will be 4 hours r 6 hours and the man who takes six shifts a week, ne a day, will receive more per hour or for the shift han the man who takes more than one shift a day.

Principles are eternal, expedients are excellent within he limits of principles. Even if I advocate expedients, go back into antiquity for principles.

What Wealth Is

An error we must banish from our minds is that ork creates wealth. Work creates production, but if nsumption equals production, there is no wealth. Vealth is the difference between production and conumption and is an individual matter. Many of us roduce, but we are not wealth creators if we consume ore than we produce. The man who produces, or arns, $1 a day and consumes $0.90 is not only a producer, he is also a wealth creator.

The man who earns or produces $50 a day and spends, r destroys, $60 is a wealth destroyer. He is like a eed in a cornfield. He utilizes his power and the ifts of nature to no purpose.

Those who are producers but also spenders often nagine that they have created existing wealth. Only so far as they saved did they create any wealth. Two men work on a house. Their labor produces it. Each receives $4 a day. One spends it all. He smokes, he chews gum, he goes to the movies, he rides on the merry-go-round, he is a devil of a fellow (it is assumed that he does not drink). The other saves a dollar a day and at the end of 10 years owns the house both built. A revolution comes. The spendthrift soviet, the communist, points to the house and says, "Behold what my labor created! Down with the bourgeoisie!" Yes, his labor created it, he was paid for his labor and he spent the proceeds as he chose.

It is a fundamental error to imagine that because I am poor someone else has grabbed off my share. If I do not breathe deeply, it is my own fault, for the oxygen is there. If I stick in a tenement cellar, the fault is mine, no one else's. I remember two cases which taught me much.

Examples of the Above Principle

Many years ago there was an immigrant garment sewer, with a large family. He lived in a New York cellar. When the spring came, he bought a tent and some cots and moved out onto the Long Island shore with his and his wife's sewing machines. Milk and vegetables were to be had from the neighboring farms, some chickens were obtained, the children weeded gardens and did other chores, they fished in the sea, they reveled in the salt water and sunlight; while he and his wife stitched. The finished garments went into the city by express, the unfinished ones came out the same way. At the end of the season his boys and girls were brown and lusty and strong, self-reliant, fed up on vitamines. Few millionaires could, or would, have done as much for their children!

The other story is of the survey of the conditions of a New England factory village, by a physician. He ascertained twelve causes for poverty, disease, misery.

The mill was responsible for a measure of bad health, because there was dust in the air, a preventable evil which it should have been compelled to remedy.

The eleven other causes were:

Bad food,	Narcotics.
Badly cooked,	Bad clothing.
Badly eaten.	Irregular habits.
Bad, unventilated living and sleeping quarters.	Personal uncleanliness.
	Sicknesses.
Drink.	Contagious infections.

This mill and its workers were wealth producers, but not wealth creators. Character had not kept pace with individual production. It is not the system that is at fault, it is the individual.

Further Examples of Wealth Production

Only a few days ago I heard of a young man who worked his way through college, who is only 35 now, who works from 8 a.m. until midnight, who has earned and saved a million dollars.

I have also watched with interest a small isolated group of foreigners in our great New York. A Jewish landlord who speaks a mangled German and an amusing English owns two houses, which he has rebuilt into room and apartment houses and rents furnished. He has obtained two Austrian families, each with male relatives. The hard working, thrifty Austrian women act as caretakers, giving maid service, the men work at their trades, and at night and on holidays and Sundays they work overtime remodeling houses. All send astonishingly generous contributions to dependent rela-

tives in stricken Austria, the young men budget their incomes and save; one of them has over a thousand dollars saved up. They are not "reds" or destroyers, they are upbuilders, wealth creators and they think the United States is a land of glorious opportunity.

Fundamentals of Wage Rate Establishment

Avoiding those two fundamental delusions of the twentieth century, that there is not enough to go around and that the unsuccessful have been deprived of opportunity, we can enumerate the few fundamentals.

The Measure of Wage

The current wage is to be measured by a time unit, as the day, the week, the month, the year. The wage earner has daily expenses for eating and sleeping, like the rates at a hotel, he has monthly expenses for bills and for rent, he has yearly expenses for clothing, for insurance, for education, for holidays, etc. As a matter of expediency in accounting, it is desirable to figure wages on an hourly basis, but the amount earned by the day or the week or the month or the year should not be lost sight of. Expenses are not by the hour, which is merely a convenient accounting unit of time.

Wage Rates Competitive

The wage rate should be the current one for similar work and skill, at the time and place. This rate is a competitive one and cannot be based on any sentimentality as living wage. We might as well understand that there are certain matters beyond human power to regulate. The sun shines and we have floods or droughts, hail falls, varying the return from the soil. We starve or we have plenty, the sun pays no attention to our living needs. We could take lessons from the frogs, biologically older than we are. When food is plenty the tadpoles to a larger extent turn into females. The race is broadened. When food is scarce, the larger number of tadpoles become male frogs, the quality of the race is improved.

The current wage, whether by the hour, day, week, month or year, should be arrived at by mutual agreement and bargaining and the agreement should be adhered to by both parties.

As an employer, I would always make the basic wage higher than the current rate in the district, not from any spirit of philanthropy but because of another great principle.

Quality, up to a certain point, increases faster than cost. This is true both as to industrial materials and as to industrial service.

High-speed steel in machine shops is worth easily a thousand times as much as carbon tool steel, but it costs only four times as much. A good leather belt costs perhaps twice as much as a poor leather belt, but will last ten to a hundred times as long and will lose 5 per cent less power, and interrupt work less often, by breaking. In Mexico I found a case where failure to obtain a good main drive belt had shut down a whole section of a machine shop for a year.

Poor medicines of insufficient strength kill thousands.

It is not the fanned almonds or peanuts I want, at their reduced prices, nor the cull fruit, nor the shoddy cloth, nor vinegar shoes and paper stockings. When I was a boy my socks were knit by hand out of handspun and hand-woven flax, sun bleached, snow water rotted. These socks wore like iron without a hole for years and years, but they cost less than I now pay for flimsy stuff.

Similarly with service work. It is not the lowest priced servant or clerk or worker of any kind who is valuable.

As an employer, I want to pay the highest, not the lowest, wages in the district. I want to pay more than the worker has individually earned.

Relation Between Wage and Service

For all wages paid there should be a definitely predetermined relation between payment and service.

It is astonishing that this fundamental requirement is still so universally ignored. In spite of decades, almost centuries, of experience, we have not yet got away from status. The horse is ours, feed him we must, as little and as cheaply as will keep him alive and in strength, and then get all the work possible out of him! This is status. Contract is something quite different. There is a definite payment per hour or per day for a definite service per hour or per day.

A good example of equivalent for wages is furnished by Henry Ford's moving assembly track. It moves at a definite rate, in an 8-hour day so many cars are assembled, the worker has skill commanding $6 per day. He must be skilled enough to acomplish what he has to do on each car, on each side of the car, in so many minutes. Henry Ford, better than any other great industrial, knows exactly what his manufacturing costs are per hour and per piece. The man cannot work faster or slower.

The fireman on an express train locomotive takes so many hours to a run and shovels on the average so many tons of coal. If the coal furnished becomes of much poorer average quality, if more cars are permanently added to the train he is entitled to a readjustment.

The living wage is sentimental absurdity. The state may prohibit me from working more than 8 hours a day and prohibit my earning less than 50 cents an hour when I work, but it cannot guarantee me 8 hours. Ten, 20, 30, 40, 50 up to 90 per cent or even more of us may be idle. Those who work receive the living wage, those who are idle starve! What they do in reality is to live off of those who are working or who did work.

The Basic Wage

This brings us to the fourth great fundamental. There is a basic wage for the trade in the district at the time. More workers will get it in flush times; good workers will get it in slack times.

Every worker is entitled to additional emoluments or to rebates for any deviation from the current standards.

The best illustration of the whole principle is found in walking. We have three elements, the walker, the weather, the condition of the road.

It is on the combination of these three that the normal performance will depend.

Normal Performance

What is normal performance? What is normal performance for heart beats, or for breathing? It is not the sudden and brief palpitation of extreme excitement, not the rapid breathing of extreme exertion. Yet also it is not the 2 minutes during which one can hold one's breath nor the rare occasion when the heart slows down or even stops. Normal performance includes both extremes. It is the total minutes of life divided into the total heart beats or the total breathings. A normal performance is therefore set up for a year at least, or

for longer, and this is wholly incompatible with any 8- or 10- or 12- or 6- or 4-hour day. We may attempt the 8-hour day, but if we adopt it as the maximum, we shall have many days of less hours and in the year average only 6 or 5 hours.

Eight hours, 6 hours, 4 hours is an industrial dream. A man should work as long as he likes to and is not overfatigued. Europe is repudiating the 8-hour day. France knows and Germany knows that working 8 hours a day Germany cannot pay the reparations and that working 10 hours she could.

This is what Keil, Minister of Labor in Württemberg, states: "If Germany is to recover from her war losses, pay her reparations and free her territory she must work 2 or 3 hours a day longer." Professor Lindemann of Cologne states:

"Germany must either lengthen her hours of work to pre-war length or she must suffer chronic hunger and suffer a rapid deterioration in national welfare and health."

Co-operation a Necessity

Chess is a very fine game. Two opponents, equally matched, sit opposite each other and each tries to do the other, to weaken him, to put him in a hole from which he cannot escape. The relations of employer and of employee have for centuries been of the chessboard type. This is unfortunate. Both cannot win. It is seldom that a game is drawn; there is generally a loser. This is not the relation between different parts of the body. The two hands, the two eyes work together. In playing a violin which hand is more important? Every part of the human body works in harmony with the other part. Employee and employer are in the same boat and neither should rock, each should pull equally, on his own oar.

How These Theories Work Out in Practice

In all the centuries there came one man who instinctively got the right idea and he has probably had less labor troubles per thousand employees than any other employer on so large a scale who ever lived. I can at least imagine his theories, which are so sane that at the start they seemed crazy.

Suppose, then, we set forth these theories in the form of a Socratic dialogue, by which method they will be made most clear to the understanding.

"Here is a new form of transportation, a self-propelling vehicle. There are 100,000,000 persons in the United States. At least 15,000,000 of them would like to have a buzz-buggy."

"Why, Mr. Ford, the farmers begrudge paying $75 for a horse buggy; the farmers did not even buy bicycles."

"It makes no difference; 15,000,000 would like to own a buzz-buggy."

"But there are no roads. That is the reason there were few bicycles far from city streets and park drives."

"It makes no difference, roads will come."

"But there is very little gasoline, not enough for 1,000,000 automobiles."

"That also makes no difference. Gasoline will come."

"But these buzz-buggies, good ones, cost $8,000 each and it takes quite a good farm to be worth $8,000."

"I expect to bring buzz-buggies down to the price of a team of horses."

"How are you going to do it?"

"There are only three elements of cost: equipment or investment costs, personal compensation costs, and cost of materials. In an automobile, whether it costs $8,000 or $300, the three elements are there and in substantially the same proportions."

"What is it going to cost to supply an automobile?"

"It will cost me exactly what 5,000,000 persons are willing to pay. If, when automobiles are selling for $2,000 a man wants to pay me $1,000, I shall furnish it, and if, when others are selling for $1,000, I find the crowd is willing to pay $800, I will built it at that price, and, if the crowd is willing to pay $600, $500, $350, I shall furnish it, still observing the proportions of perpetuation of investment costs, personal compensation costs and material costs."

"Do you mean to say that you can reduce the investment charge to one-third?"

"Yes, by working my equipment continuously. If the same machine makes each 24 hours three times as many gasoline tanks, the investment charge drops to one-third."

"But how about wages? A man cannot work 24 hours a day, like a machine, and turn out three times as much."

Man as the Machine Supervisor

"No, but the modern idea is that man is a supervisor of equipment, a handler of materials, not a muscular drudge like a mule. There is no limit to the amount of equipment a man can supervise, nor to the amount of material the supervised equipment will handle. Therefore, to reduce the man cost to any extent desired, all that is necessary is to obtain more intelligent men than the average and I obtain such men by paying them more."

"But what about materials? A car's weight has not dropped to one-third."

"The actual first cost of steel and of rubber and of wood is very small, the scrap value of a car is at most 2 to 3 cents a pound. All the rest is equipment and personal compensation cost, and by enormous production these can be brought down.

"What is the method?"

"It is very simple. We find that we can sell cars by the million if they cost only $300 each. Let us assume that the three costs are, for perpetuation, $75; for personal compensation, $75; for materials, $150. Can a $6 a day man do all the work on a car in 12 days? He must! We can give him the machines to do it!"

What Will Follow the General Adoption of These Theories

The possibilities in this line are beyond belief. I have seen a material and man cost of $6 reduced to 6 cents, a labor cost of $25 reduced to 5 cents. I have seen a wise investment of $100 in equipment reduce man cost more than $100,000.

The wage question is, therefore, not whether the employer can do the employee, nor the employee do the employer, nor yet whether both can extort high prices for small quantities from the purchaser; but whether a fair ratio can be established between perpetuation costs of equipment, personal compensation costs and machine costs.

If the relation is established and if all three combine, the result is vast quantity at low price to the public, opportunity to invest largely at low rates, high compensation to skilled men for short hours.

New York City.

Measuring Administrative Efficiency

The Problem of Administration Today — Fundamental Questions of Administration—The Questions Can Be Daily Answered by the Intelligent Use of the Proper Control Charts—The Time Concept of Administration Is the True Basis of Control

By Walter N. Polakov
Of Walter N. Polakov & Co., Inc., Engineering Counselors

THE post-war industrial situation has shifted the administrative center of gravity from making workmen personally efficient to making administrative organization flexible enough to meet the rapidly changing situation.

We have developed a high state of technique, especially in chemical and metallurgical industry, because of a broad application of engineering research. Theoretically and practically competent chemists and engineers are available; workmen, seeking steady employment rather than high wages, readily develop necessary skill under competent training; but administrative leadership meets with new difficulties.

Problem Before Industrial Administrator

To analyze a situation, first of all intelligent questions must be asked; then these should be answered. Men of average intelligence seldom know how to formulate a question; men of higher intelligence can ask clear and definite questions; but only trained men in each profession can both put a question and give an answer to it.

The problem before an industrial administrator of today is not only that of formulating pertinent questions in order to bring forth the nature of the rapid changes in industry; not only to answer these questions, thus pointing out the relation between cause and effect; but, essentially, to act according to the facts disclosed and thus get things done.

Place of the Industrial Consultant

It might be well to leave the analysis of the situation and the interrelation of changing causes and effects to the care of trained and experienced industrial diagnosticians, who, by virtue of their profession, have a horizon broader than any one plant or any one industry; who, thanks to years of experience in various fields of industry, have acquired the technique of putting questions and evolving answers; who, for this purpose, have devised a method of informing the administrators with the least loss of time and energy and with the utmost accuracy and precision what to do and when to do it, leaving the question of how to do it to the technical staff of the organization.

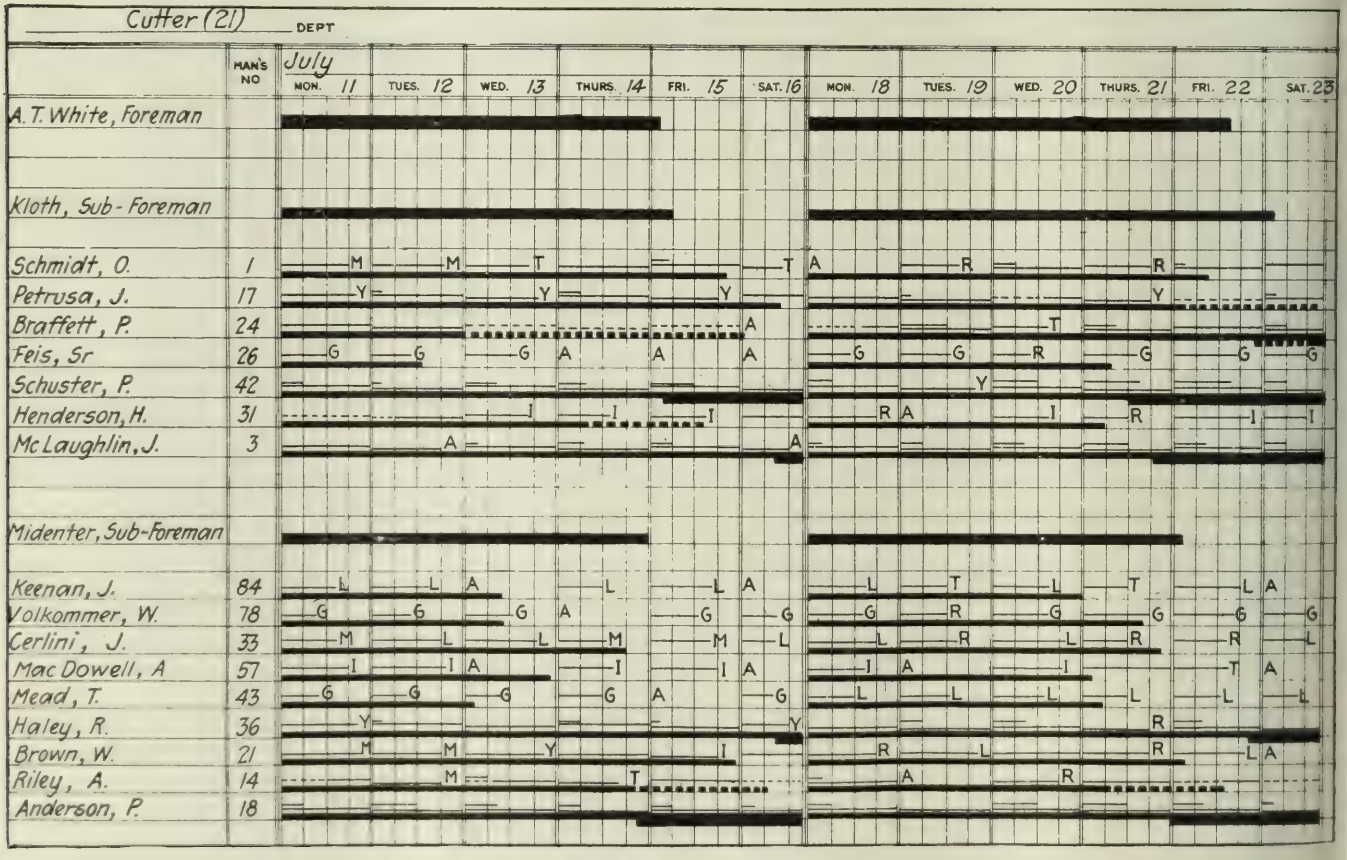

FIG. 1—MAN RECORD CHART.

Each daily space represents the amount of work to be done in a day. If less was made, the thin line is drawn proportionately shorter; if more, the lines are doubled up at the end. Broken lines indicate time taken for jobs about which it was not known how long they should take. Heavy lines are the summaries of the work done per week. Thus one of the subforemen got out more than 4 days' work in a week while another just 4. The next week the first subforeman got out more than 5 days' work in a week while the second was still a day behind. Letters after short bars denoting less work done in time allotted indicate cause of delay thus: *A*—absence of operator; *G*—green operator; *T*—tool trouble; *I*—instructions missing; *M*—material causing trouble, etc. When the trouble is so known, it enables those responsible to find a means of eliminating it.

WORKING PERIOD ~ WEEKS One DAY PERIOD ENDING ____ 19 Sample from a Textile mill

TONS	DEPARTMENT OR MACH CLASS	% OF CAPACITY USED ON ____ TURN (10 20 30 40 50 60 70 80 90)	DETAILS OF EXPENSE OF IDLENESS DUE TO: LACK OF ORDERS	LACK OF HELP	LACK OF MATERIAL	REPAIRS	POOR PLANNING	EXPENSE OF IDLENESS: TOTAL	UNAVOIDABLE %	UNAVOIDABLE AMOUNT	INCREASE IN EXPENSE OF PRODUCT %	AVOIDABLE	REMARKS
	Spinning		$18.70					$18.70					
	Winding			103.74		15.00		118.74					
	Doubling		10.61					10.61					
	Twisting		17.93					17.93					
	Quilling		10.67	10.00				20.67					
	Warping				390.75			390.75					Lack of Wound Yarn
	Weaving		75.00		840.25			915.25					Lack of Warps
	Finishing				210.72			210.72					Lack of Woven Goods
	Inspecting			10.70	39.00			49.70					"
	Shipping		66.00		150.17			216.17					" "
	Total		198.93	124.44	1630.89	15.00		1969.26					

FIG. 2—MACHINE RECORD CHART

The idleness of productive capacity indicated by this Gantt chart is also interpreted in terms of expense involved. Mill that had on hand enough work to keep 80 per cent capacity busy (spinning) produced only 55 per cent of total output, having large portion of the equipment idle for various classified reasons. Note how delay in hiring winders reflected in heavy losses in warping, shortage of warps caused idleness in weave shed, etc., down the line. Such knowledge readily directs the efforts of executives toward the trouble at its origin and enables them, through knowledge of the cause, to find the remedy.

Fundamental Questions for Administrators

The fundamental questions that must be asked and answered in any industry, in any establishment, are:

1. Is the most needed work done first and will it be completed in time? If not, why not?
2. Is the plant equipment utilized to the fullest extent? If not, why not?
3. Is the available knowledge and skill applied in the fullest measure? If not, why not?

There might be an endless number of other questions asked; but the answers to all must be deferred until the replies to these three cardinal questions are daily received and use is made of these answers.

Figs. 1, 2 and 3 suggest the graphic method of getting the necessary facts for answering the three questions just mentioned.

A more specific instance taken from files of one of our clients shows by chart how the record of fuel utilization in a power plant reflects not only a better utilization of available knowledge and skill, but simultaneously provides management with an accurate means of measuring the quality of work and provides men with stimulating scores of their game against bogey—a standard of perfection toward which they are making marked progress.

Proper Measurement the Basis of Administrative Control

The practical task of controlling production must of necessity begin with measurement; and, to be correct, measurements must be made in the proper dimension. It would be a grave blunder to apply a unit of one dimension to an entirely different dimension, or to use a measurement which contains a variable element. We cannot use for measuring human work the units of mechanical power such as foot-pounds or horsepower, which would embrace only the muscular work of men, even though these expressions contain the time rate, for it would be a confusion of a part with the whole. This time rate of man's work is the only measure of production which is of the same dimensionality as the energy causing it and it is as constant as the solar system itself.

Since time may be spent for different purposes and the amounts of work that can be done in a unit of time may differ of necessity, the scales may be as varied as are human activities themselves; but we cannot conceive human activity without or beyond time.

Charts Which Answer the Questions of the Administrator

Time, in its relation to our existence, is divided into present, past and future. Hence we have three fundamental managerial problems visualized in three forms of charts: applied to the present or to current work, the Man Record Charts; referring to work done in the past, the Machine Record Charts; and projected to future work, Progress Charts, with their schedules laid out on the time scale of future requirements.

The Man Record Chart

During the time devoted to productive work there is a variable amount of work done, and this is what is shown on the man record chart, but this work is performed and directed by men. "To feel the lure of perfection," says Prof. C. J. Keyser, "in one or more types of excellence, however lowly, is to be human; not to feel it is to be subhuman." And a chart of this kind involves that ideal of service. It shows what is expected to be accomplished within the work time for any occupation, however lowly.

In such a chart this ever-striving impulse of self-expression in service which throbs in every human being is given adequate expression and stimulus. It is accomplished by predetermining the ideal, however modest, which is accepted by a man as within his power of attainment. Then, and only then, can the lines of attainment be drawn from day to day to denote falling short of the aim, or equaling, or surpassing it, as the obstacles of inertia, ignorance or lack of co-ordination are overcome by the strongest of all human propensities

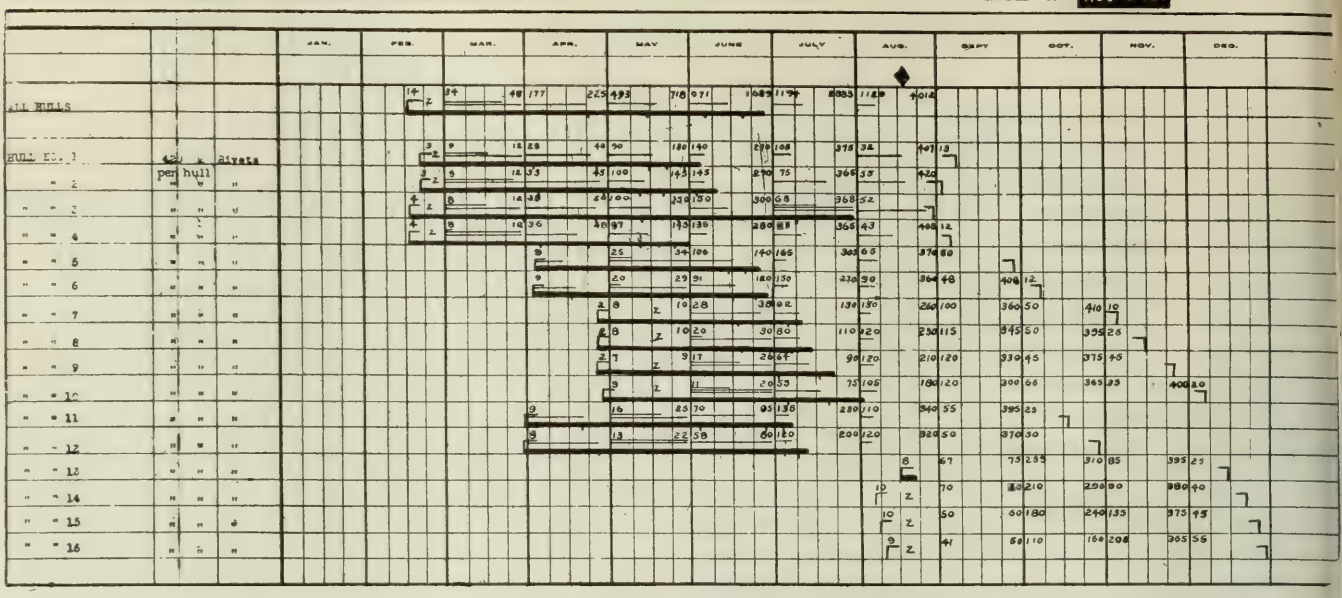

FIG. 3—PROGRESS CHART

Each hull of the sixteen boats under construction was scheduled for completion at the time marked by a half bracket]. In the middle of August (when this chart was entered) the work was about 7 weeks behind the promise. Amount of work done on each hull during each month is shown by thin lines and cummulative total by heavy lines. Numbers on the left of each monthly space show the number of rivets that are scheduled for that month, and on the right the number to be completed by the end of the period. For instance, the record of the hull No. 3 indicates that in May only 50,000 rivets were driven instead of required 100,000, while in July two and a half times more was done than scheduled in order to catch up, or 170,000 rivets instead of 68,000. Same principle and method are equally applicable to any factory, department, contract or activity.

—the desire to excel oneself. This type of chart can truthfully be called a tool for humanizing industry, for it not only reveals to a man his own dignity and capacity as a creator, but subtly, though persistently, calls for co-operation between brain and brawn in accomplishing the work. It tells what each and all are doing at present.

The Machine Record Chart

The machine record chart reveals to one who reads between the lines much more than merely the time a certain machine was idle. Its scale is also time; but the time during which a machine remains unproductive has a graver significance than a reminder that "time is money." It means that someone, who should have operated it or supervised its operation, did no work; and the time of inventing, developing and building this machine, which is greater in its productive significance than the time of the operator, is irretrievably lost.

The Material Utilization Chart

The material utilization chart—like the charts already shown — indicating the waste of material or energy, also has a deeper meaning. It shows the extent to which the work of other men in recovering, preparing and delivering this material or energy has been destroyed. It means that the work of hosts of other men has been rendered useless and their productive time forever lost. This type of chart gives us the measure of our utilization of work that has been done before. It proves whether we are worthy of our inheritance from the past.

The Progress Chart

The progress chart integrates all elements of work; it sums up the progress made, its acceleration, its retardation, its time rate. Like other charts, it brings together the ideal and the fact. Its ideal projects into the future and sets before us the task which we are called to perform—no matter how small or how great it may be—whether filling an order in a shop, feeding a nation, or advancing the life and happiness of mankind. It calls for a plan and vision of the future. It is based on knowledge of the past and it reveals our position at present.

This Time Concept Is the Basis of Efficient Administration

The time concept in the control of industry, direction of production and measurement of human work thus stands revealed as the wished for solution, free from errors of confused types and dimensions. It refers all facts to the irreducible and final element of human life—time. Because it is true to the human dimension, it is both human and humane; hence it obliterates conflicts between men and management, promotes the fullest exercise of man's creative forces and places work in its proper relation to life.

Such and similar work of engineering administration and industrial counselor prompted our great American mathematician—Prof. C. J. Keyser—to define engineering as: "The science and art of directing the time-binding energies of mankind—the civilizing energies of the world—to the advancement of the welfare of man."

This definition itself is but an apt formulation of the admirable time-binding work done by some of our leaders and an excellent example of the far-reaching implications of Korzybski's concept of man as the time-binding class of life. It is indeed, highly significant that Calvin Rice, secretary of the American Society of Mechanical Engineers, in a recent message called the attention of the engineering profession to this function and responsibility.

To measure the time-binding quality of industrial administration is today beyond any doubt a task before which any other transient problem shrinks into insignificance.

Steam for Power and Process in the Chemical and Allied Industries

General Considerations in the Use of Steam—Control System Should Be Simple and Thorough—Establishing This Control System Through the Work of a Test Engineer—Functions of the Test Engineer in Boiler Room, Engine Room, Distribution System and Process Work

By Herbert B. Reynolds
Mechanical Engineer

With the increasing cost of coal and other fuel, more and more attention is being given to its economic use. Even in the large power stations, where there has always been more or less stress put on the efficient use of coal, the managements are constantly on the lookout for means of reducing the consumption of coal. However, it is in the smaller industrial plants that the greatest opportunity lies for conserving fuel.

It has been the author's experience that even in some of the best-managed establishments, where the most modern methods are applied in the manufacturing end, wastes have been permitted to go on in the boiler and engine rooms without receiving notice. As long as the voltage is on the line and the steam and compressed air pressures do not fall too low, there is no complaint. However, in the meantime it may be costing twice what it should cost to maintain the service.

The Reasons for Inefficient Methods

This general inefficiency in the industrial plants is often due to the fact that those responsible for the management of the factory are specialists in the manufacture of their particular product and have no interest in the power end, which is in most cases quite foreign in nature to the manufacturing end.

I have known cases where a piece of equipment has been purchased for the manufacturing end of an establishment, the use of which may give a moderate return on the investment; while, on the other hand, the veto has been put on the purchase of some inexpensive equipment for the power house which should pay for itself many times within a year. The reason for this, as above mentioned, is that the management knows nothing about the power end; and, furthermore, it does not want to know anything. Often the only thing known about the power plant is that it is a necessary evil, and can cause a lot of trouble if it has to shut down for any reason or other.

Power Costs Should Be Determined

All modern manufacturing plants maintain a very extensive and detailed cost system, from the records of which the cost on each particular manufacturing operation or process can be obtained with the highest degree of accuracy. If the cost of any particular operation or process takes a sudden jump, a lot of explaining has to be done. In addition to this, a corps of experts is employed to make time studies, motion studies, etc., in an endeavor to reduce costs. However, a great many of those well-managed plants do not know how much a pound of steam or a kilowatt-hour of energy costs them, although these costs may form no small part of the total manufacturing costs. The power station costs in these cases are generally thrown in with the overhead, where it is difficult to detect any variations due to inefficiency in the use of fuel.

Fundamental Costs in Steam Production

Where records are lacking, the means for determining these records are generally lacking. Most plants know how much coal they use during a period, say a month; but a great many have no means for determining the output of their power department. Without knowing the output of both electric and steam power, no check can be kept on the operation of the plant. In order to obtain the output no very elaborate equipment is required in most cases. It is difficult to make any general recommendations as to what records should be obtained, as the class of service in various plants varies so much.

There are, however, two items which should be obtained in every plant. They are the amount of coal burned and the amount of water evaporated into steam. By knowing these two items, the efficiency of the boiler room operation can be determined. It may be well to state right here that this item is one of the most important for the management to watch, as there is no other place in the plant where more loss can occur due to indifferent labor. The determination of the engine room efficiency is a more difficult matter, especially in those plants which render various kinds of service such as electric power, compressed air, high- and low-pressure steam, refrigeration, etc. However, an endeavor should be made to obtain such records by means of which a check of the engine room performance can be had.

Reports on Steam Generation

As to just what records the management should have submitted daily, weekly or monthly, this is also difficult to outline so that it would be applicable to all plants. However, this report should be very brief and contain only those items which are of direct interest to the management, such as total coal consumed, water evaporated per pound of coal (boiler efficiency), total kilowatt-hours of electric power generated, etc. It is often desirable to submit this report in graphic form so that any change in the performance of the plant will stand out and be easily detected.

Control by Means of a Test Engineer

In order to inaugurate a system as outlined above, a young technical graduate should be employed. This position should be filled with great care. A man who has had several years' experience in the efficiency department of some large central station should be obtained.

He should possess tact and initiative; and should have a pleasing personality which will enable him to gain the confidence and good will of the operating men in the boiler room and engine room. The title of this man should also be selected with care. Titles such as efficiency engineer, betterment engineer, etc., should be avoided, as titles of this nature are apt to prejudice the operating men against him. The title of test engineer will be satisfactory in most cases. The test engineer should report to the man who has general charge of the power department.

It should be impressed upon the test engineer that everything he does should have either a direct or an indirect bearing on the improvement of economy. Otherwise there may be a tendency for him to make the place look like a Christmas tree by installing all kinds of instruments, and to fill the files with high-brow technical reports containing the results of elaborate tests. On the other hand, it will be necessary for him to run certain tests and collect data which will be of no interest to the management and which may appear to be useless.

Isolated Plant or Central Station

There is one question which manufacturers who use more or less electric power generally ask themselves, and that is whether or not they could save money by purchasing their power from the nearest central station. This question cannot be answered until each case has received very careful engineering study. In general, if the power consumption is large compared with the demand for low-pressure steam for heating or process work, then it may pay to purchase power. However, in most chemical industries, with the exception of those employing electrolytic processes, the demand for power is small compared with the steam load. In these cases it is doubtful if any saving can be accomplished by purchasing power, especially if the private plant is fairly well managed. However, as stated above, this question can be answered only after a very careful study of each plant. There are, no doubt, a few places where a combination of central station and private plant service would be the cheaper.

Boiler Room

The boiler room in most private plants is generally the last place to receive any attention in so far as the adoption of modern and efficient methods is concerned. A low type of indifferent labor is also generally found in most industrial boiler rooms. This is most unfortunate, because it is in the boiler room where the greatest loss can occur due to lax methods. The impression seems to be that the only qualification needed for a fireman is the ability to shovel coal. Actually, a boiler should be under the direct supervision of a highly trained man, as the real work of a fireman is to watch and regulate a more or less complicated chemical reaction—that is, the combustion of coal. The chemical engineer would not think of leaving one of his departments, where an important chemical process was being carried on, in charge of unskilled laborers. However, this is exactly what is done in the average industrial boiler room. The result is that loss occurs due to the improper mixing of the two raw materials—that is, air and coal.

Control Instruments

One of the first things that should be done is to provide instruments which will tell the fireman whether or not he is obtaining the right mixture of air and coa There are several types of these instruments availabl some of which are better suited than others for th work. It may be well to mention here that all instru ments should be selected with great care. After ir struments have been installed, they should receive regu lar attention from some one man who should be hel responsible for their operation. Nothing will caus the operating man to distrust scientific methods mor than a lot of instruments in a plant which are out o order half the time. After the installation of thes instruments the men should be furnished with shor non-technical instructions as to how to use them.

Next to the proper handling of the fires comes th proper maintenance of the boiler room equipment, suc as the condition of the furnace brickwork, boiler heat ing surface, both internal and external, baffles, etc There are all matters which the test engineer shoul follow up.

The Question of Coal

Coal is the greatest item of expense in the operatio of any power plant. For this reason, it should be pur chased with the greatest care. The first question tha should be asked in regard to the coal is whether o not the right kind of coal is being used. The price ma be right, but the coal may not be the most economical The selection of coal requires a great amount of carefu study, as there are a great many factors to be con sidered, the most important of which are the type o stoker, furnace, the analysis and the price of the coal None of these items can be considered independent o the others. It is impossible to give any detailed in structions in an article of this kind as to the selectio of coal. However, an attempt will be made to point ou in a general way those factors which should be con sidered. The type of the stoker equipment will decid as to what general class of coal should be used.

After this has been decided upon, the analysis o several coals of this class should be studied. One o the most important characteristics of the coal which should be considered is the heating value. However the mistake should not be made in thinking that this is the only characteristic worth considering. The per centage of ash has a most important bearing on the value of coal. A paper presented before the June, 1922 meeting of the American Society for Testing Materials entitled "A Rational Basis for Coal Purchase Specifications," by E. B. Ricketts, treats the subject of the selection of coal in a very thorough manner. A rough rule which may be used is that each 1 per cent reduction in the heating content of a coal reduces the value of that coal from 1 to 2 per cent, and an increase of each 1 per cent in the ash content reduces the value from 2 to 3 per cent. This rule covers increase in coal- and ash-handling costs.

Influence of Coal on Power Plant Capacity

The quality of coal has a very important bearing on the capacity of a plant. There are probably instances where additional boilers have been added when this could have been avoided by changing to a different coal. Even if the new coal costs more, it may be cheaper to use it than to add boilers. It is quite often possible to double the capacity of an existing boiler plant by simply changing the stoker equipment. In view of this, those plants which are pressed for boiler capacity should look carefully into the possibility of changing either the coal which is being used or the stoker equip-

nent, or both, before buying additional boilers and adding to the boiler house.

After making a preliminary selection of coal, it should be tried out in the plant before the contract is signed, as the analysis will not always give an indication as to how satisfactory a coal will burn under actual operating conditions. It may also be well for the test engineer to run a set of boiler tests in order to determine the efficiency, maximum capacity obtainable, etc. After a coal has been definitely decided on, a set of specifications should be drawn up and incorporated in the contract. These specifications should provide for a bonus and penalty if the coal in any particular shipment is better or poorer than that called for by the specifications.

Limitation of space does not permit giving any detailed directions for drawing up a coal contract. This should be one of the duties of the test engineer. When coal is bought by specification, it is necessary that samples be taken from each shipment and analyzed. This should be a very easy matter in a chemical industry where laboratory facilities are available. Although not the largest source of loss, the amount of unburned coal which is rejected from the furnaces should be checked up by taking periodic samples of the ashes and analyzing them.

Treatment of Feed Water

Another matter which deserves investigation in most small plants is the treatment of the boiler feed water. This is a subject which should be of interest to the chemical engineer; and at the same time there may be possibilities of saving if given proper attention.

Considerations of Load

The test engineer should look into the question of the number of boilers which are being used in cases where the plant contains a number of units. The general tendency is to use all the boilers in the plant, although it may be possible to carry the load on a fewer number, resulting in a saving of coal. This, however, depends upon the character of the load. If the high loads are of short duration and it is necessary to carry banked boilers a large part of the time, then the chances are that no more boilers should be fired than are absolutely necessary to carry the maximum load. On the other hand, if the load is very steady throughout the 24 hours, it may pay to use all the boilers in the plant. As mentioned above, this is a matter for the test engineer to study.

Too much attention cannot be given the general appearance of the boiler room. The windows should be kept clean, the walls whitewashed or painted and the lighting properly arranged and kept in good order. If the boiler room is kept in good order and clean, it will be easier to obtain and keep the right kind of firemen.

Engine Room

Although there may be some opportunity for improvement in the engine room, there is less chance for any great loss due to poor operation than in the boiler room. If engines are used, the setting of the valves should be checked up from time to time by the test engineer. In the case of turbines, a careful watch should be maintained over the conditions of the blades, clearances, etc. The surface of condensers should be kept clean and means should be provided for measuring the amount of air leaking into them. The air which can leak through a small pin hole may cause a loss of hundreds of dollars in a year.

Exhaust Steam for Process Work

At one time a great loss occurred in many industrial plants by using high-pressure steam for various manufacturing processes and heating where low-pressure steam taken from the exhaust of engines or turbines could have been used. The exhaust steam from an engine or turbine contains almost as much heat as live steam and thus is almost as useful.

With the development of the bleeder turbine great improvements have been made in this direction. In cases where all the exhaust steam cannot be used in manufacturing processes, the bleeder turbine offers a means of operating the turbine partially condensing, resulting in low steam consumption, and at the same time steam at any desired pressure can be drawn from it for use in manufacturing processes, after it has generated a certain amount of power. If all or nearly all the exhaust steam can be used in processes or for heating, the fuel costs for power is almost nothing, as the turbine simply acts as a reducing value and at the same time generates power. If there is a surplus of exhaust steam, which is either being condensed or discharged to the atmosphere, each process using high-pressure or live steam should be carefully studied in an endeavor to substitute the use of low-pressure steam.

Distribution System

The most characteristic feature about a great many distribution systems is the lack of system. This is generally caused by the gradual growth of the industry. It is very difficult to reconstruct a distribution system without a great deal of expense. Nevertheless, in many cases it is possible to make improvements at a very small cost.

The covering of steam pipes should receive very careful attention, not only in order to conserve fuel but to keep the temperature of the working rooms down to a minimum during hot weather. All steam lines should be carefully drained of condensate. One of the greatest hidden losses in a distribution system is caused by leaky traps. If the system is a large one, it will pay to employ a trap inspector whose duty would be to make periodic inspection of all traps. If conditions permit, the discharge of all traps and any other condensation should be returned to the boiler room and used for feed water. There are several advantages in doing this: First, the water is recovered; second, the heat in the water is conserved; and third, condensation is almost free from any scale-forming elements, making excellent feed water.

Present Status of the Use of Steam

During the last few years great strides have been made in the conservation of heat in various chemical processes. An example of this is the development of multi-stage evaporators in which steam is used to evaporate a liquid, the vapor of which is passed on to a second evaporator, where it is condensed, and at the same time the heat is used in evaporating another liquid. In this manner the heat in the steam is used over and over again in carrying on several distilling operations.

Where an industry consists of several departments, means should be provided for measuring the amount of power and steam consumed by each department. If this is done, excess consumption can be traced.

Good Lighting
A Servant That Will Increase Production

Artificial Illumination a Necessity — The Advantages to Be Derived From Good Artificial Illumination — Relative Cost of Good Lighting Referred to the Cost of Labor—The Importance of Proper Distribution

By Charles Gallo
Illumination Bureau, Westinghouse Lamp Co.

IN THE industries, artificial illumination is an investment in superior management. Primitive man with his "pine knot" torch and modern man with his "billion candlepower" searchlight both found and find artificial light a necessity. Notwithstanding the progress which man has made in the field of artificial lighting—a progress whose alpha and omega might be represented by the pine knot with its smoke and yellow flickering light and the modern minute and highly efficient tungsten lamp used on the surgeon's or the dentist's probe—the real need for effective artificial illumination is not always clearly realized.

The surgeon and the dentist recognize and appreciate the value of modern illuminants. The industrial executive, to whom effective and adequate illumination on a broader scale may render as great a service, is frequently too busy with other and perhaps more pressing problems to consider the subject of artificial light. Yet this subject handsomely repays consideration.

Advantages Derived From Good Illumination

Briefly summarized, the advantages derived from good illumination are:

1. Increased production.
2. Reduced accidents.
3. Greater accuracy in workmanship resulting in improved quality of the products manufactured.
4. Less eye strain, thus increasing the efficiency and health of the workers.
5. Working conditions more pleasant, with greater contentment of employees and a reduction in the labor turnover.
6. More order and neatness in the plant and pride in its appointments.
7. Supervision made easier.

These advantages are very real and they are obtainable at very moderate cost. The details of working out a satisfactory lighting installation may be delegated to an illuminating engineer, and the manufacturers of lamps are always ready to supply advice without charge to their customers. The executive or manager owes it to himself, however, to see to it that this phase of his supervision is not neglected.

Increased Output Through Good Illumination

Adequate and effective illumination has increased the output of various manufacturers from 5 to 20 per cent. In some cases even higher increases have been observed. These increases are due to the fact that with good light the workmen can *see faster*. The truth of this statement may be easily demonstrated in your own shop. Go near some machine with a fairly large flywheel or gear. The apparent speed at which that wheel revolves will depend on the amount of light that falls on it. Obtain a lamp and a reflector (about 200-watt size) direct a strong light suddenly on the moving wheel, and you will see it *slow down*. Does the speed of the wheel actually change? No! You can *see* the spokes *more quickly* and the wheel *seems* to go slower.

EXAMPLE OF GOOD GENERAL LIGHTING

The same things happen in any operation which requires manual attention. It takes time for a workman to see and to pick up a given tool. Increase the light on that tool and the operation is speeded up unconsciously and automatically. The man moves faster because he sees faster. The truth of this has been demonstrated time and again in machine shops, foundries, textile mills and other industries.

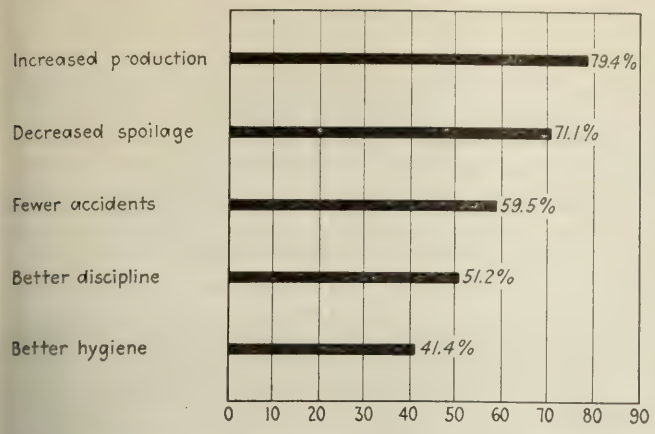
Cost of Lighting Referred to Cost of Labor

Many industrial executives have realized the advantages which good lighting carries with it. They are cashing in on their realization because they have installed modern and effective lighting systems and they will never go back to the old. A few are named:

Phelps-Dodge Corporation, Nocozari, Sonora, Mexico.
Chapman Valve Co., Indian Orchard, Mass.
Millers Falls Paper Co., Millers Falls, Mass.
American Steel & Wire Co., Worcester, Mass.
Alabama Pipe & Foundry Co., Anniston, Ala.
Columbus Forge & Iron Co., Columbus, Ohio.
Conner Steel Co., Birmingham, Ala.

The cost of good illumination will of necessity be variable. Two and one-half per cent of the wages is, however, a trustworthy average figure. Wages represent about 20 per cent of the value of the finished product. It follows that the cost of good lighting is in the neighborhood of one-half of 1 per cent of the value of the product.

We have previously noted that production is frequently increased from 5 to 20 per cent, due to good lighting. Were production increased only 7 per cent,



BETTERMENTS EFFECTED BY GOOD LIGHTING

the money invested in good lighting would be earning interest at the rate of 1,300 per cent. Isn't good lighting an efficient servant?

Accidents and Waste Eliminated by Good Lighting

The report on "Eliminating Waste in Industry" issued by the American Engineering Council's committee attributed industrial waste to a number of factors, among which are:

1. Low production—caused by faulty management, faulty equipment and plants.
2. Lost production—caused by ill health, physical defects and industrial accidents.

The same report stated that the responsibility for over 50 per cent of the waste in industry lay with the managers of the various industries.

Above we have hinted at the fact that managers may decrease some of the waste due to *low* production by improving lighting conditions. Waste due to *lost* production caused by accidents and ill health may also be reduced by good lighting.

Fig. 1 shows how darkness or inadequate lighting and accidents go hand in hand. Accidents are not all due to poor lighting conditions. Statistics show, however, that accidents may be reduced about 20 per cent by improving lighting conditions. Records for the year 1919 show that 23,000 fatal or crippling accidents caused a loss in time equivalent to $853,000,000. If good lighting reduced accidents by only one-eighth this would represent a saving of over $100,000,000. Is that worth while?

In this article we have thus far mentioned good lighting and adequate lighting. It will probably be well to define these terms, to try to explain what is good and adequate lighting.

What Is Good Lighting?

Daylight and plenty of it, shaded and softened, is both good and adequate. How good and how adequate is perhaps best realized by the illuminating engineer, who must try to produce equivalent results, by using that wonderful, if small, substitute for the sun, the modern incandescent lamp. The human eye can, when not imposed upon by glare, adapt itself to operate over a stupendous range of illumination values, and the illuminating engineer can therefore obtain good results with the means already at his command.

Adequate lighting is that which will supply an illumination of such a value as to enable a given operation to be performed most rapidly. Illumination from the quantity standpoint is measured in foot-candles. Ten years ago 3 foot-candles was considered good illumination for weaving operations in a cotton mill or for grinding or mixing in a chemical plant, because any more light was prohibitively expensive. Today 10 foot-candles is considered good lighting for the same purposes, and costs less. It may be that 10 years hence still higher values will be considered desirable. As competition increases and with it the necessity of more and better production, good illumination is found more and more profitable. The modern factory lighting codes such as that issued by the Illuminating Engineering Society give the values of illumination which are now considered adequate for the various industrial processes.

Distribution of Lighting Important

Good lighting combines an adequate illumination with a proper distribution of the light. If you are reading a book or a paper some sunny afternoon, you will probably turn your back to the sun, in order to avoid the annoying glare. If the paper is white, you will move it into the shade. By so doing you improve, in so far as you are concerned, the distribution of sunlight on your reading matter. For this reason bare lamps cannot supply good lighting. They must be equipped with proper reflectors in order to shield the eyes from the annoying and blinding brightness of the lamp filaments and also to direct the light where it is needed—where the work is performed.

Artificial lighting is paid for on the basis of kilowatt-hours. You pay for the same amount of current whether you use it as heat or as light. Since you are purchasing light, the moral would be, get as much of it as possible for a given expenditure. To do that, use efficient lamps. The light-producing efficiency of the modern lamp increases with the size or the wattage of the lamp. Other things being equal it is more profitable to use large lamps and fewer of them, than a multitude of small lamps.

Lighting Trend Toward General Illumination

The trend of good lighting in today's industries is toward general illumination, using large shielded lamps wherever possible. The limiting factor is generally the height at which the lighting equipment can be mounted. For given types of reflectors the ratio of spacing to mounting height is constant and must not be exceeded when good lighting is required throughout a given area.

General illumination is the lighting system "par excellence" for chemical plants. In these plants maintenance of equipment is at times a veritable bugbear. General overhead illumination, by reducing the number

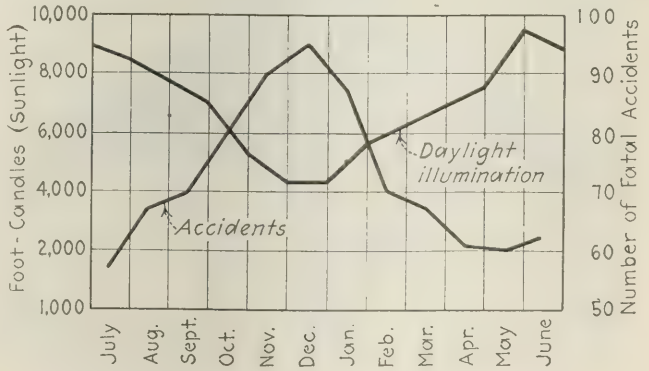


FIG. 1—SEASONAL VARIATION OF FATAL ACCIDENTS

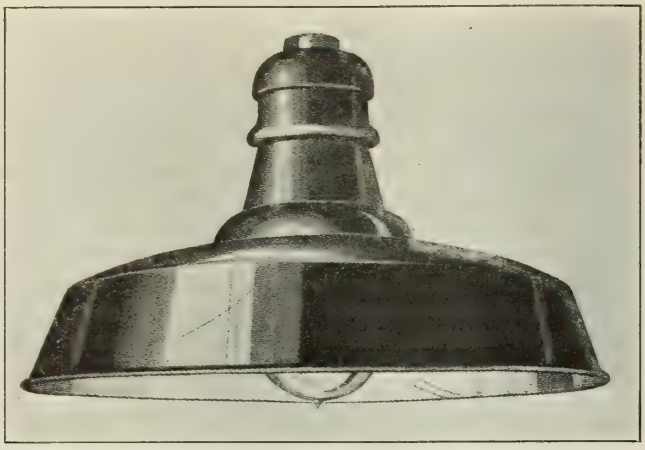

FIG. 2—STANDARD REFLECTOR FOR INDUSTRIAL USE

of outlets, greatly simplifies the maintenance problem, lowering depreciation costs and also the cost of installation.

In such plants good porcelain-enameled steel reflectors, with self-contained sockets such as shown in Fig. 2 will give excellent service. Where corrosive fumes or explosive gases are present in considerable quantities the vapor-proof type of unit (Fig. 3) will give the most satisfactory service.

Points to Be Observed in Maintenance of Lighting System

The most efficiently designed and constructed lighting unit can give good service only when it is kept clean. In buildings with high ceilings, where general overhead illumination and high (18 ft. or more) mounting heights are used, reflectors equipped with pulley-sockets or with automatic cut-out hangers will be found to simplify the cleaning problem greatly. It should also be remembered that where the equipment is kept clean, it not only will deliver all the light paid for but it will also depreciate more slowly. This is particularly true in chemical plants.

Another point worth considering in industrial illumination is the effect of voltage on the light-producing characteristics of modern incandescent lamps. Lamps operating below their rated voltage dissipate current as heat. A lamp operating at 4 per cent below its rated voltage will produce 15 per cent less light than one operating properly. If you buy light, operate your lamps at their rated voltage.

The industrial executive of today is interested in reducing operating costs, in increasing production and in eliminating wasteful methods. Good illumination is not an absolute panacea for all these ills, but can be a mighty helpful agent. It can increase your production, make your plant a better and more satisfactory place to work, reduce your labor turnover, improve the morale of your employees.

A very effective servant at your command. Put it to work.

New York City.

FIG. 3—VAPOR-PROOF REFLECTOR FOR CHEMICAL PLANT USE

Compressed Air as an Aid to Production Efficiency

Most chemical plants have compressed air available for process work. The full compressor capacity is seldom used in the processes; and there is an excess available which may be employed for blowing out pipe lines, cleaning motors and other equipment and for supplying power to various tools used by the plant maintenance department.

There are, however, some other uses to which this excess air power can be put which are a distinct aid in saving man power and increasing the operating efficiency. These uses embody the employment of the pneumatic hoist, an efficient and cheap tool which has not had the general recognition it deserves.

The Pneumatic Hoist

The typical pneumatic hoist has been brought to a a high state of efficiency. The air motor has double acting, cylinders, placed at right angles and operating on a single-throw, balanced crank shaft which is connected to the drive. This drive generally is of the worm gear type, and is cut to a pitch that insures locking of the drum and holds the load at any point, even when the air is turned off or the line breaks. With this feature the load can be raised, the air line disconnected, the hoist run on a trolley, to a distant point, another line connected, and the load placed as desired. Such a hoist can be operated at a cost of less than one-thousandth of a cent per foot of lift per 100 lb. lifted.

Some Uses for This Hoist

One of the most efficient methods of material handling in chemical plants involves the use of electric trucks or tractors and trailers. A good many of the loads encountered are too heavy to be conveniently lifted to the platform of the truck or trailer. If a pneumatic hoist, mounted on a trolley and track, is arranged to serve each station where trucks or trailers are to be unloaded or loaded, this work can be done in the cheapest and most convenient manner.

In many chemical plants we meet the problem of handling large steel drums, which, when loaded often weigh 1,000 lb. or more. It may be desired to lift the empty drum to the filling station, to move it after filling to the heading machine, from there to the scale and from the scale to storage or shipping. Many plants where this is the case are not large enough to warrant an extensive handling system and the air hoist solves their handling problem well.

The Relation of Safety to Increased Production Efficiency

Incentives to Accident Prevention—How Safety Is Achieved in Several Large Industries—Losses Through Preventable Accidents—How Safety Work Increases Production Efficiency

By Louis Resnick
Assistant to the Director, Safety Institute of America

WHEN Judge Gary in 1908 issued the memorable order which started the safety movement not only within his own company but in American industry generally, he had only one thought: to prevent, so far as humanly possible, loss of life or maiming of men through industrial accidents. The humanitarian appeal was the sole impelling motive in the case of practically all of the pioneers in the industrial safety movement.

There were no compensation laws in those days, and if anyone had suggested the possibility of preventing accidents and increasing production by the same stroke he undoubtedly would have been laughed at. The Steel Corporation and the other pioneers in the movement were quite willing to spend millions of dollars to safeguard life and limb in their plants without any expectation of a financial return through increased production. They were, in fact, reconciled to a lowering of production through accident prevention activities, for the earliest safety devices and educational methods were crude affairs.

Incentives to Accident Prevention

As soon as the Steel Corporation had demonstrated that it was actually possible to reduce accidents, industrial men throughout the country began to give serious attention to the accident causes in their own plants and to means of eliminating them. Then came the wave of compensation legislation, a decade or so ago, and this drove thousands of manufacturers who were not inclined to mix sentiment with business into accident prevention work as a matter of self-preservation. Safety does decrease compensation costs, and that fact soon became the second great impelling force in the safety movement in America.

But today there is a third incentive for giving serious attention to accident prevention in industry, and that is the effect of such activities on production efficiency. The chemical and metallurgical industries are rich in examples of safety work which also—sometimes by design and sometimes much to the surprise of the safety engineer himself—increased the production of the individual machine or workman, decreased the production costs through some other means, or increased the quality of the product.

One of the big paint manufacturers set out to eliminate the health hazard to the men in his principal manufacturing department, and in revising its processes with that one end in view, stumbled upon a means of increasing his production efficiency through all three of the channels just enumerated. What started as a bit of safety work in this plant has revolutionized a century-old manufacturing process. Today this company is engaged in tearing out equipment which is being replaced by new machines occupying approximately a fifth as much space and which turn out a better and cheaper product with a very heavy reduction in the number of lead-poisoning cases among its employees.

In the so-called dope room of the Armour & Co. can factory at Chicago there is another good example of much the same thing. In this room there are a dozen or more oven-like machines known as compound driers in which the grooves of can covers and bottoms are coated with a benzene composition. For years this department justified its name. Operators and inspectors at the driers would become "dopey" and frequently would actually fall asleep at work. It was difficult to retain employees in this department, and a great deal of time was lost through headache.

"My principal job," the foreman tells us, "used to be to walk from machine to machine and talk to the operators and inspectors so as to keep them from falling asleep."

Perhaps the most expensive result of this condition was the heavy percentage of defective can covers which were passed by the semi-conscious inspectors. Every defective cover sent to the canning department meant a leaky can and spoiled food. The "leakers" sometimes ran as high as 7 to 10 per cent—quite an expensive item when you consider a production of 50,000 cans a day. Sometimes the room became so full of fumes that the department had to be shut down, and this in turn meant the temporary closing of the entire can factory and the can-packing departments.

Remedy for the Fume Hazard

Then along came the superintendent of the can factory and, independently, hit upon the same scheme that solved a somewhat similar problem at the plant of the Ford Motor Co. He devised an exhaust system to draw off the benzene fumes, the pipes of which ran directly into the drying machine instead of terminating in hoods several feet above the machine, and in addition he installed another set of pipes through which fresh air was constantly blown into the room. This enabled the department to increase its production 25 per cent, to get a much better class of employees, and to retain them; it made possible so much better inspection that this department received a large share of credit for the reduction of "leakers" from an average of 4 per cent to less than one-half of 1 per cent; and there hasn't been a single case of an operator or inspector falling asleep in this department since.

An Example at the Ford Plant

The experience of the Ford Motor Co. presents this example. There is in one of the buildings at the Highland Park plant a department including ninety-seven cyanide furnaces and seventeen annealing furnaces. Up to 2 years ago this department was one of the most troublesome in the plant. The furnaces were heated to 1,560 deg. F. and it was necessary for the workman, standing directly before the open furnace doors, to work in a temperature of 133 to 135 deg. It was impossible to keep men in this department for any length of time, and during the summer months eight to ten cases of heat prostration a day were a common experience. The situation became so serious that the general super-

intendent, P. E. Martin, made a special study of the department and as a result a metal canopy was placed around each furnace, making possible the continuous exhaustion of the hot air. At the same time cold air was blown down on the heads of the furnace tenders, bringing the temperature where the men worked down to 80 deg.

This installation was completed at a cost of $100 per furnace—$11,400 in all. And this is how Frank Donovan, superintendent of the department, described the results: "The canopies have done away with heat prostrations in this department, the labor turnover has been reduced 25 per cent, the output has been increased, and our working force has been reduced 50 per cent. This ventilating installation paid for itself the first month in the saving of labor alone, by enabling one man to take care of two furnaces instead of one as before."

An Example From a Dye Plant

The dye works of E. I. du Pont de Nemours & Co. at Carney's Point, N. J., affords still another example. The operation necessitated the constant employment of two workmen to shovel the material into barrels and their consequent exposure to fumes. During July and August of 1919 work on this operation was stopped; the drying operation was replaced by an automatic machine which discharged directly into carriers, where the material was permitted to drain before being dropped into the barrels; a new neutralizing plant was installed with proper fume exhausts; a new catch tank was installed; and the wooden platforms were replaced with concrete. When the process was started up again in September production materially increased, while the number of industrial malady cases decreased.

Loss Through Preventable Accidents

So much for specific instances. The loss to industry as a whole through preventable accidents and preventable illness runs into billions of dollars annually, and few industries are immune. For instance, every morning when the whistle blows more than a million workers are missing from their benches. Every day 3 per cent of all workers are absent on account of sickness. At the very low average wage of $3 a day this means a yearly loss of over a billion dollars in wages and an additional equal amount lost to employers through the disorganization of their working forces. The waste in industry survey conducted by the Federated American Engineering Societies disclosed the annual loss of another billion dollars through accidents. The full significance of these two tremendous items of loss to industry becomes apparent when we accept the statement of safety engineers and industrial physicians that 75 per cent of all industrial diseases and industrial accidents are preventable.

Production Increased by Safety Work

Probably the greatest opportunities for increasing production efficiency through safety work lie in such simple mediums as lighting and ventilation. The bureau of illuminating engineers of the New York Edison Co., which has conducted a good deal of research along these lines, for instance, reports the following as results of revision of lighting facilities in industrial plants:

Increased production	79.4 per cent
Decreased spoilage	71.1 per cent
Reduction in accidents	59.5 per cent

The library of the Safety Institute of America contains many records of marked reductions of accidents in plants in the chemical and metallurgical industries. Each such reduction spells increased production efficiency. The methods of preventing industrial accidents are neither secret nor mysterious. There are in the United States several national and scores of state or local safety organizations where employers interested in the subject may meet and exchange experiences. There is an abundance of literature on the subject, and several safety museums, the oldest and largest of which is the American Museum of Safety in New York City. The employer who is interested in accident prevention or who wishes to learn of the possibilities in this field today has everything in his favor and nothing to hinder him.

New York City.

The Dollar Side of Safety

In an editorial in the *National Safety News* for June, 1922, Holger Jenson makes the following pertinent comment:

"The idea of safeguarding human life and limb is as old as history, but the introduction of modern machinery brought an economic loss, through industrial and public accidents, that fast became a menace to the nation's future welfare. At first, the safety movement was accepted, not as an economic proposition, but strictly as a humane one. The extensive precautions necessary to prevent accidents meant a financial outlay and were observed only to a limited extent; beyond a certain point safeguarding methods were looked upon as extravagance.

Safety Precautions in a Steel Mill

"I recall a steel mill which reached its peak in the number of accidents, including three fatalities, all within a period of 90 days. Suggestions for the adoption of safety precautions and devices were received by the remark that a steel mill could not be operated without accidents; that it was impracticable to fence in the mill equipment. The workmen themselves showed an antagonistic attitude toward the installing of safeguards. The management, however, agreed to make some of the improvements which, from a humane standpoint, were considered necessary. Great was the surprise when it was found that not only were the accidents greatly reduced, but the output of the plant increased. The company at once proceeded to go the limit in safeguarding and in convincing the workmen of the importance of being cautious—all of which involved a large monetary expenditure.

"After a period of one year, the general manager stated that the money invested to prevent accidents had paid better dividends than any other similar outlay he had ever made for production.

Ventilating System Pays Dividends

"In another case poisonous dust and fumes destroyed the vitality of the workers, greatly reducing production. Working hours were reduced, but still the management had to refuse orders, it being impossible to fill them. The installation of a ventilating system solved the dilemma. In the manufacturer's own words, "Our output is twice as large as before, with the same number of employees; the company and the workmen are making more money than we ever dreamed of and everybody is healthy, happy and contented.' That manufacturer and his employees now appreciate the dollar value of safety."

The Budget as a Means of Industrial Control

Successful Conduct of Business Must Be Based on Facts—The Elements of the Cost of Manufacture—Analysis of These Elements the Basis of a Budget—How a Budget Helps the Manufacturer to Control His Business

By Walter Rautenstrauch
Vice-President, J. G. White Management Corporation.

THE unusual circumstances surrounding the conduct of business affairs during the past several years have impressed manufacturers and others with the fact that many of the rules of business procedure upon which they had depended in times past were not adequate to meet the new conditions. Old standards by which progress was measured, costs determined and results predicted proved faulty, with the result that losses arose where there should have been profits and many business enterprises failed which should be in satisfactory operation today.

It is unfortunately true that overspeculation in markets and inventories is responsible for the situation in which many manufacturers find themselves today. Aside from the fact itself, it is unfortunate because it has misled some to overlook the real reasons which underlie embarrassing situations for which the failure of the market cannot be held responsible. When judgments were based on adequate facts—not mere records, but facts—there were rarely any occasions for excuses in regard to lack of profits.

Necessity of a Means of Forecasting

Many a business man, looking toward the future, is asking himself if there is not some means by which he can foretell and thus control the situations he will have to meet; does a business have to be run on an emergency basis or can it be operated with a reasonable knowledge of tendencies and the consequence of these tendencies. It is no tax on the imagination to contemplate the fact that nothing ever happens by chance. In every field of activity, whether in the chemical laboratory or in the business office, there are natural laws of action and reaction which are irrevocable, and success depends upon conformity to these laws.

Nature of the Economic Problem in Business

The chemical and metallurgical sciences have made more progress than economic science because chemical reactions are of relatively short duration, so that facts are immediately discerned and easily impressed upon the mind. In economic science the reactions are of longer duration, covering periods of months, or even years; and the results are often obscure because they are remote from the causes. We fail to appreciate the warnings of our physician because we are not immediately a candidate for the hospital when we do not regulate our diet or procure glasses or take exercises prescribed. I am inclined to believe that the same psychology is operative in our attitude toward business problems.

We seem to need a more fundamental basis for the exercise of competent judgment on business problems. One step toward this end appears to be in the use of a budget system of control by means of which proper standards are set up and performances compared with these standards.

There is scarcely a business enterprise which does not have some method of accounting by means of which periodic statements are prepared showing the results of operation of the business. A careful analysis of these operating statements will show for any business that the elements of the cost of manufacture are as follows:

1. Fixed charges, which do not vary with the rate of production or quantity produced in a given period. Such charges are depreciation, interest on funded indebtedness, insurance, local taxes, salaries of officials and office help, etc.
2. Variable charges, which vary with the rate of production or quantity produced in a given period. Such charges are indirect labor, indirect materials, supplies, sales commissions, etc.
3. Direct materials, varying with the rate of production.
4. Direct labor, varying with the rate of production.

Analysis of Accounts

Unless the accounts have been classified with some reference to the uniformity of the items of expenditure grouped under each account, the operating statements must be very carefully examined if a reasonably accurate determination of the above elements of cost is to be made. It must also be recognized that certain major items of expense are of a dual character with respect to their relation to the volume of production. The cost of power, for example, has certain elements which are fixed and others which vary with production. Insurance against fire, etc., is fixed; but employees' liability insurance varies directly with the payroll and hence with production.

The operating statement examined may also contain certain items of expense which are abnormal for the period covered by the statement. Major repair charges, for example, accumulating in any period must be distributed over the time during which the wear occurred. So also there may fail to appear in the operating statement certain charges which should normally appear, but which have been covered by expenditures in prior periods. By the exercise of a little common sense, one may take an operating statement covering a given period and determine the cost items which are normal; and by comparison with the sales accomplished during the period arrive at ratios of fixed charges, variable charges, direct labor cost and direct materials cost, to sales, which are very useful in establishing the essential cost characteristics of the business.

A Graphic Analysis to Form the Basis of a Budget

These values may be used to set up a graphic analysis as shown in Fig. 1, which relates to a certain manufacturing plant recently examined by the writer. Analysis of the operating statement shows that for a volume of sales of $650,000 the direct labor is $130,000, or 20 per

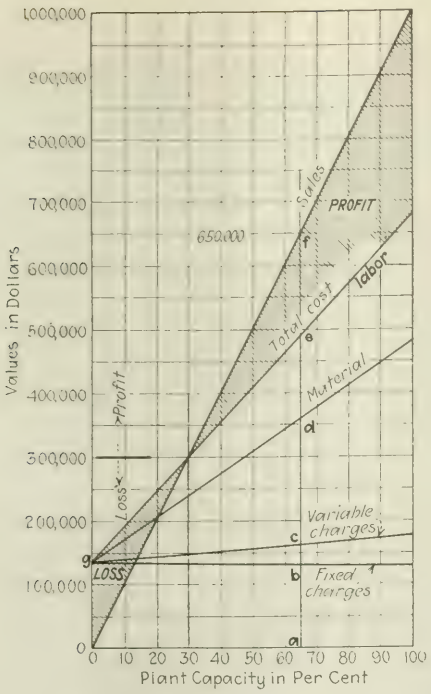

FIG. 1—THE GRAPHIC BASIS OF A BUDGET.

cent of sales. The direct materials cost is $195,000, or 30 per cent of sales. The variable charges are $32,500, or 5 per cent of sales, while the fixed charges are $130,000. The plant is producing $1,000,000 sales annually. These values are set off in Fig. 1 as follows:

Let the ordinates represent dollars value and the abscissas percentage of plant capacity. At 65 per cent of plant capacity, which represents $650,000 sales, erect an ordinate and set off

ab equals $130,000 equals fixed charges
bc equals $ 32,500 equals variable charges
cd equals $195,000 equals direct materials cost
de equals $130,000 equals direct labor cost
af equals $650,000 equals sales

Construct *of*, *gb*, *gc*, *gd*, *ge*.

How the Graph Is Made

The intersection of *of* (sales line) with *ge* (total cost line) will indicate the volume of sales at which the company will "break even." In this case the sales must be at least $25,000 monthly, or $300,000 annually, before profits begin. This analysis is in many respects very valuable to the plant management. It establishes a budget limit of expense for labor, material and overhead (variable and fixed charges) for different plant outputs, with which the actual costs of these items may be compared and the profitableness of the business approximately established. These budget items may be subdivided to any degree which the requirements of the business may demand, and comparisons may be made not only with the total but with the elements which make up each major item.

Some Uses of the Graph

This analysis establishes the danger point of the business below which losses are incurred. It may be used to determine the effect of changes in material and labor costs, or changes in sales price, on the profitableness of the business. It indicates the variation of overhead with plant output. If, for example, the overhead (variable plus fixed charges) is estimated as a percentage of direct labor cost, it will be found that at 40 per cent capacity the labor cost is approximately $75,000 and the overhead is $150,000, or 200 per cent of labor. At 75 per cent capacity the labor cost is approximately $150,000 and the overhead is $165,000, or 110 per cent of labor. At 100 per cent capacity the labor cost is $205,000 and the overhead is $180,000, or approximately 88 per cent of labor.

If, for example, it has been the custom to base a cost estimate on an overhead of 100 per cent on labor, which may be satisfactory when the plant is operating at about 80 per cent capacity, the same percentage when used for a 40 per cent capacity will result in the determination of a selling price which will not cover costs. Competition may of course fix the price at which goods may be sold, and the situation may have to be met regardless of the plant capacity being used. Nevertheless the facts of the actual costs incurred should be faced, for nothing can be gained by a false method of cost determination.

In times such as the present, when plant output is below normal, it is very important for the manufacturer to know how the overhead varies with plant output, as indicated by the above illustrations. The all too frequent custom of using a fixed percentage for overhead, regardless of output, is very dangerous. The above analysis may be made for each department of a business as well as for the business as a whole. This is particularly valuable in case a variety of products is being manufactured and the profitableness of each line is to be determined from time to time. The industry as a whole may be profitable, yet certain products may be sold at a loss.

An Example From Practice

In a plant examined by the writer some time ago it was the custom to use 100 per cent on labor cost to cover overhead in preparing cost estimates. It was true that for the plant as a whole one dollar was spent in overhead for each dollar of productive labor cost. It was also true that the several products made by the company did not pass through the same departments. Some products were made in departments in which the factory overhead was 300 per cent on labor, and other products incurred a factory overhead of only 50 per cent on labor. The result was that some products were sold at a loss, while others were sold at a high profit; and also that orders were readily booked for the products which were underestimated, and the business in the higher priced products was not readily obtained.

Advantages Following Use of a Budget

There are many factors which control the successful operation of a manufacturing plant, and one cannot hope to correct all unsatisfactory conditions by merely establishing a budget system of operation. It is believed, however, that a prediction of expense items for varying plant capacities, such as is briefly set forth above, will be very helpful to many manufacturers who have never attempted it. Standards will be established which are useful not only in cost determination but also in measuring decreases or increases in given expense items. One never hears of a race being run to determine the distance which may be covered, say, in 10 minutes. The race is run over a measured course. The race for profits is, no doubt, governed by the same principles.

Cost Accounting And Factory Efficiency

The Technical Executive Who Uses His Cost System Without Being Dominated by It Is Well Equipped for Intelligent Control of the Factors for Efficient Production and Distribution

By George P. Comer
Chief Accountant, United States Tariff Commission

THE basic reason for a cost system in manufacturing establishments arises from the continual development of industrial technique into more and more complex forms. In the days of rule-of-thumb methods both in production and management serious errors of judgment were corrected by personal observation in the plant or sales department. Under modern conditions no such personal contacts can be established, and a substitute for them must be found. This substitute is in large measure supplied by the cost systems in operation in the modern factory. Only rarely, if at all, can the manager follow the daily and hourly movements of materials through the plant in the literal sense, but the "shadows" or "echoes" of the operation may pass across his deck in the form of cost and production records. It is not meant that the management may properly sit at desks a thousand miles away and look at paper slips to the exclusion of actual contact with the factory, but a man with some imagination, corrected periodically by personal observation, may reproduce in his mind a whole series of operations by examining well-organized cost records.

If the development of cost and production records has resulted from the growing volume and complexity of industrial processes, it follows almost necessarily that the records will be more or less behind the pace of industry. During the rapid expansion of the dye business, for example, in 1919 the chief accountant for a large dye plant informed the writer that although he visited the works weekly his records by processes were always several weeks behind the actual methods of operation. For that reason the management was seriously handicapped in correcting errors of production by study of the paper records. The redeeming feature in the situation was the fact that both the accounting force and the management knew that the records were lagging behind the factory processes and consequently many accountants were employed to keep up with the changes in the plant.

Attitude of the Management

If flexible and progressive cost records are required in a modern factory, so likewise must the mind of the man who interprets them be flexible and progressive. This is no place for an essay on managerial qualifications, but the bias of managers is so pronounced in many cases that the best cost system may be rendered nugatory or even positively harmful by the use that is made of it. So well defined are some bias attitudes that textbooks have begun to name them "production bias," "cost bias," "sales bias," etc. Some men, for example, are dominated by the cost records to such an extent that they see no inconsistency in charging, or attempting to charge, $2.50 for a product one month and $3.50 for it the next month. The "cost plus 10 per cent" theory figures out that way, so what more can be done?

On the other hand, many men are convinced that the main function of the management is to sell goods, leaving the weather and the factory superintendent to determine costs. At times, in periods of chaotic costs or uncertain markets, the records of the past or even the cost of the day may be temporarily neglected, but in the long run unless the cost of produtcion dominates the sales policy dividends will fall off. In some cases sentiment or the necessity of a full line may dictate that some products should be sold at a loss, but as a general rule that management is most successful who first discovers the cost of production for all lines and then gradually lops off the unprofitable parasites.

There is a sense, however, in which, under certain conditions, it may be profitable to sell at less than the so-called cost of production. This situation arises when the "marginal cost," as the economist would say, is different from average costs. Every superintendent knows that although the cost of the average product in the factory may be $10 per unit, yet at certain times, especially in slack periods, additional units of the same product may be manufactured for a cost of $5 per unit. Under such conditions it may be advisable to fill some special orders for less than the average cost. Stated in other terms, these marginal orders will be profitable if the price is anything above the actual cost of material and direct labor which go into the fabrication of the article. Stated in still another way, any portion of the general overhead expenses borne by the marginal orders is a gain for the year's operation.

It will be recognized that this obvious industrial fact may cause more harm than good when practiced by indiscreet executives. The temptations to overexpansion, cut-throat competition and ill-advised booking of orders when the factory is already under full production may turn the scale from profit to loss. "Marginal orders" become "average orders" under such conditions, and the full market price must be charged for them. In short, it is a wise man who can use his own cost system without being dominated by it.

Cost Accounting and the Control of Production

In order to show the function of a cost system in relation to the control of production it is necessary to outline some elementary principles of cost accounting.

In the first place, cost accounting must not be confused with the regular routine of bookkeeping which most plants carry on. Bookkeeping is a record of the past. Cost accounting is largely estimates for the future. In every well-organized system there are two streams of records flowing side by side, with occasional junctions between the streams. The one stream is made up of the multitude of cost records, which enables the management day by day to estimate the cost of the processes current in the plant. The other stream is the regular course of bookkeeping which, for the most part, records actual transactions. The purchase of raw material, the payment of wages and the cost of repairs

flow along under the hands of the bookkeeper into the monthly trial balances, balance sheets and profit and loss statement. Such a stream may go on with little or no reference to the unit cost of production of particular products. The cost stream is much more intimately connected with the manufacturing processes. Weekly, and daily if necessary, the management may know approximately where it stands with respect to any order on its books.

The two streams touch and, in a sense, become identical at the end of the fiscal period. Cost estimates are matched against actual expenses, and adjustments for errors are made. The ledger record of the past fiscal period becomes the basis for the cost estimates in the future period, and in all cases the basic cost accounts must be closed out into an account representing the cost of the finished product where the cost stream is set over against the income stream from the sales department. This twofold relation of the cost and ledger records is fundamental. On the one hand estimates of the current and future costs must be based on the facts of the past and on the other hand such estimates must be checked against the actual annual expenses when the bookkeeping records are finally closed.

Failure to make such adjustments is often serious and sometimes ludicrous. One company whose books were recently examined by the writer charged to the cost of production interest on the investment for every department in the factory. Having charged the interest to cost, the bookkeepers neglected to tie the cost records to the bookkeeping records by crediting the interest account, and therefore Profit and Loss, with the amount imputed in the cost charges. The result was that they had large hidden profits that appeared nowhere in earnings—6 per cent on the whole factory investment of about $10,000,000.

Basic Schemes of Distribution

To the superficial observer there are almost as many cost-accounting systems as there are independent manufacturing establishments. Each one seems to be different from the other, and in the eyes of the accountant, especially if they have been long accustomed to one system, their own methods seem unique when unrelated to that of any other establishment. To the experienced accountant, however, who is not confused by details, it is equally obvious that fundamentally there are only two or three different cost systems. The chief differences in most systems grow out of the methods of distributing overhead expenses. The costs of material and of direct labor are relatively simple. Therefore they are not the chief points of interest in the system.

So complex is the allocation of general expenses to the cost of particular products, however, that several different schemes of distribtuion are current at the present time. In general these may be divided into distribution on the basis of direct labor, on the cost of material, the value or quantity of output, the departmental investments or the cost of machine operations. Each of these methods may be further subdivided into more refined or, as some would say, more sophisticated processes of distribution. Direct labor, for example, may be considered from the point of view of man-hours or from the point of view of labor cost. Distribution on the basis of material may be either in proportion to the cost of material or to the quantity used. In some cases the quantity or value of both labor and material may be combined in arriving at a basis of distribution. Another method often used in the chemical industry may be called the "process method," by which all possible charges are allocated to different unit processes such as grinding, nitrating and sulphonating, after which the general expenses not chargeable to any process are distributed in proportion to the various process costs in the factory. Perhaps the most detailed and in some respect the highest type of cost accounting grows out of the machine cost method of distribution. The particular type referred to is usually called the "machine-hour" method—that is to say, all possible cost items are centered upon a machine, or more properly upon each type or battery of machines, and the cost of operating one of them for an hour is determined. In some cases the machine operator himself is considered an adjunct to the machine and his wages are charged in with the cost of operating the machine.[1]

The Essential Elements of Cost

The main elements of the cost of operating a given class or battery of machines are as follows: First, the cost of the space which they occupy; second, the fixed charges on the machines, such as interest and taxes, whether they are in operation or not, and third, the direct cost of operating them. These main divisions of expenses are further subdivided into a multitude of items involved in the operation of the factory. Schematically the main elements of cost may be outlined as follows:

ELEMENTS OF COST OF MACHINE-HOUR

I. Space cost:
   1. Interest on real estate.
   2. Repairs.
   3. Taxes.
   4. Depreciation.
   5. Insurance.
   6. Light and heat.

II. Fixed charges on the machine:
   1. Interest on the machine.
   2. Repairs.
   3. Taxes.
   4. Depreciation.
   5. Insurance.

III. Operating charges:
   1. Repairs and depreciation from use.
   2. Oil and waste.
   3. Share of foreman expenses.
   4. Power.
      A. Power cost consists of:
         1. Space cost, fixed charges and operating charges on the machinery in the power plant.
         2. Fuel.
         3. Labor, in power plant.

From the strictly accounting point of view each of these subdivisions of cost is worthy of lengthy consideration, but for present purposes a bare outline of the method of determining the machine-hour rate from these cost elements is all that is necessary. The machine space cost is determined by allocating to a particular battery of machines space charges according to the ratio which the battery occupies to the total machine floor. If a battery requires one-tenth of the total factory space for operations, other things being equal it should receive one-tenth of the space charges. The fixed charges and many of the operating expenses are directly chargeable to the machines. Power is allocated to them by various methods commonly known to the engineering profession. When the total cost of maintaining and operating a machine is determined for the fiscal period the "machine-hour cost" is obtained by dividing the total cost by the number of hours the

[1] It should be understood that in the following discussion the term "machine" is not necessarily limited to a single mechanical unit made up of wheels, cams and pulleys, but it may include a whole installation of process equipment or in fact any arbitrary group which operates more or less as a productive unit.

machine was in operation during the period. Thus if all charges, such as rent, interest, depreciation and operating costs for a machine are $1,000 for a year and the machine was in operation 2,000 hours during the year, the "machinery-hour rate" is 50 cents per hour. In other words, during the subsequent fiscal period each job will be charged 50 cents per every hour the given machine is used on it.

The Departmental Cost Sheet

Having determined the machine-hour rate and caused each production order to be charged with the machine-hours expended upon it, the next step is to assemble the charges against each order in the various departments. For illustrative purposes a hypothetical Departmental Cost Sheet is shown in Fig. 1. It should not be assumed that this exact form can be used in practice, because, for the sake of brevity, more classes of departmental expenses are assembled on it and each class is shown in briefer form than is feasible in practice.

DEPARTMENT COST SHEET

Production Order #1001. Department D.

MATERIAL

Description	Amount	Unit Cost	Value	TOTAL
Total			$20.00	$20.00

Man Number	Machine Number I	II	III	IV	V	Man-Hours	Rate per Hour	Amount
10	5	3	2	2	1	13	$.50	$6.50
11	3	2	1	1	1	8	.40	3.20
12	3	3	2	1	1	10	.35	3.50

Idle Cost	$...	.33	.20	.52	1.80	Total Idle Cost		$2.85
						Superintendent and Management		10 00
						Other General Expense		5 00
						GRAND TOTAL		$65.00

FIG. 1—A HYPOTHETICAL DEPARTMENTAL COST SHEET

The first significant figure on the Departmental Cost Sheet is the "Production Order Number." The "Production Order" is the beginning and end of real cost accounting. This order, signed by someone in unquestioned authority, starts the process of manufacturing and its final O.K. is the record of a completed job. By it the unending stream of production is broken into sections or units for costing purposes. These units may be determined by a given quantity of output, such as would be occasioned by manufacturing goods to order, or they may be determined primarily by time periods. Each day or each week a new production order may be initiated whose size is fixed by the predetermined factory output for the season or fiscal period. Each order bears a number and all records pertaining to it must show the number in unmistakable figures.

Heading the tabulation of each Departmental Cost Sheet is a record of the material used for this production order in the department. In the lower checkerboard table is the record of labor and machine cost. The columns "machine number" and "man number" record the number of machine- and man-hours required on the order. As a matter of fact, each man number in practice may stand for a whole group of men whose hourly wage is the same and each machine number may represent a battery of "machines"—vats, nitrators or equipment of various kinds.

After the record of each man and of each machine is compiled on the sheet, calculations of costs are made. The total machine-hours for each machine are added in the perpendicular columns and these sums are multiplied by the particular "machine-hour rates," which rates were determined in the manner indicated in the previous discussion. The man-hours are added horizontally and the sums multiplied by the wage rate per hour. By adding these results the total direct labor cost and the total machine cost on this order for this department is obtained. Other departmental charges not included in the machine rate, such as superintendence and management of the factory, may be included at the bottom of the sheet as indicated.

The Costs of Idle Equipment

On this form there will be noted the cryptic expressions "idle rate," "idle cost," etc. These items are sufficiently important and sufficiently different from other cost items to justify their being written in red in practical accounting. They refer to the burden of idle time imposed upon this order by the idle machines and equipment. A clue to the calculation of idle cost is given by the fractional index numbers accompanying each machine number. The fraction ⅔ connected with machine III for example, means that, in the last fiscal period, this unit ran on the average two-thirds time. The record of idle hours for this production order is derived by the use of this index. Obviously there will be no idle time for a machine when it is occupied on a production order (unless of course there is time occupied in the preparation and setting up of the machine), but each hour a machine works on an order must bear a proportionate share of the idle time expenses for the fiscal period. If a two-thirds time machine is used 10 hours on a job, then the other one-third for idle time must be included in the cost. If it has been determined that the idle rate or fixed charges on a machine is 25 cents per hour and the machine is used 10 hours, then a simple calculation gives the idle charge. ⅔ = 10 hours, ⅓ = ½ of 10, or 5 hours, and $5 \times 25 = 125$ cents, the idle cost for machine III on this production order. The idle charges for all the other machines are similarly calculated for each particular order and a total idle cost is written in red at the place indicated in the form.

It will be observed that this total idle cost is not carried over into the main cost column for the depart-

ment. It does not follow, however, that the idle charge is not in total cost. As a matter of fact, this amount is included in the machine cost item discussed above. It will be recalled that the total cost of the machine for the entire year was divided by the actual number of hours the machine was in operation during the year. This gave a machine-hour rate which automatically takes care of all idle time charges. If a machine was in operation 2,000 hours out of a total of 3,000 hours for the year, the machine-hour rate would be 50 per cent greater by dividing the total cost by 2,000 than it would be by dividing it by 3,000. These hour rates then, when applied to the machine-hours on this job, give a machine cost which includes the idle time charge.

The reason for stating idle cost separately is found in its paramount importance in factory management. The red figures are a record of inefficiency—a mark of failure as compared with a perfect co-ordination of operating factors.

The Indices of Maladjustment

The indices themselves assume great importance to the discerning manufacturer. Sometimes the idle time charge is large because of business conditions over which the management has little control, but in many cases they hang on month after month because of maladjustments within the factory. Some simple arithmetic applied to these indices gives an interesting result. It will be observed that the least common denominator of the fractions $\frac{2}{5}$, $\frac{3}{5}$, $\frac{3}{4}$, $\frac{3}{4}$ and 1 is 60. If the denominators are raised to 60 the numerators become 24, 36, 40, 45 and 60. That is to say, under the given conditions, if the department had sixty batteries of type I machine, forty-five units of type II, etc., down to twenty-four units of type V, all machines could be run full time so far as the physical organization of the department is concerned. Under the conditions assumed on the cost sheet, however, machine V, operating only two-fifths of the time, can take care of the full-time output of machine I, while number III can perform its share of the operations in two-thirds of the time.

The indices likewise suggest the idea that there are recurring sources of good and bad adjustments within the factory. A given plant with a well-balanced equipment may begin to show heavy idle time charges when enlargements are undertaken, and only after the next common denominator is reached will the balance be restored. It is not implied that in actual practice any such simple arithmetic as this can eliminate idle time, but if the factory is carefully scrutinized for these causes of maladjustment a substantial reduction in idle time charges will result.

Another difficulty met with in the treatment of "idle time" arises in periods of depression under severe competition. It was stated above that the idle time charge is included in the cost of production through the machine cost figure. However, in the recurring periods of depression when competition is keen, these expenses may so burden particular products that market prices cannot be based upon cost figures which include idle charges. When half the looms in a textile mill or half the equipment in a chemical plant is idle, any attempt to make the small volume of products actually sold bear the full overhead charges for the whole plant may result in prohibitive prices. Under such conditions the management should temporarily charge the expense of idle machinery directly to profit and loss rather than in detail to particular products. Here again the executives must be the complete masters, so to speak, of their cost system and must know precisely what loss each underpriced order involves if disastrous results are to be avoided by the competitive price policy.[2]

Cost and Sales Summary

In the previous discussion attention has been centered on a departmental cost sheet. Another tabulation of even more importance than this sheet is the Cost and Sales Summary, in which is assembled the cost of each order from all departments and the sale or market price of the product. Such a summary is illustrated by the form reproduced in Fig. 2.

In the first place, it will be seen that the detailed cost of each production order is shown both by departments and by cost elements such as material, labor and overhead expenses. Beside the total cost for the order is placed the selling price, and this figure is followed by the loss or gain on the order. The idle time charge for each department is repeated and the totals for each job are shown. This is a statistical figure, however, because, as stated above, idle charges are included

[2]From the foregoing discussion it appears that idle time is the *bête noir* of factory management. The writer knows personally of but one case in which idle machinery was a blessing. In a chemical plant near Philadelphia there is one department idle the year round, but figuratively, if not literally, the dust is brushed off the machinery every morning. The product formerly made in this department is purchased under contract from a competitor. Once a year as the time for the renewal of the contract approaches the competitor is given a good lunch and shown through the idle department for a white-glove inspection. The management is then ready to talk business for the coming year.

COST AND SALES SUMMARY

Production Order #1001

Departments	Material	Labor	Machine Cost	Supt. or Mgnt.	Sundry Expense	Total Cost	Selling Price	Loss or Gain	Idle Time Cost	Machine-Hours	Man-Hours
A	$20	$10	$7	$2	$1	$40	....	....	$1.75	30	32
B	25	15	12	6	2	60	....	....	3.00	42	45
C	18	7	5	2	3	35	....	....	2.00	29	30
D	20	18	12	10	5	65	....	....	2.85	49	49
Totals	$83	$50	$36	$20	$11	$200	$225	$25	$9.60	150	156
			Production Order #1002, etc.

Cost ledger estimates	$4,000	$3,500	$3,000	$2,000	$1,000	$13,500	.....	.....	$1,100	900*a*	1,300*a*
Actual costs from ledger	4,000	3,800	2,900	2,200	950	13,850	$20,000	$6,150	1,050	1,350*b*	1,350*b*
Error in estimates		300–	100+	200–	50+	350	.....	.....	50+	450*c*	50*c*

a Actual machine- and man-hours from job sheets. *b* Full-time factory hours. *c* Actual idle hours per period.

FIG. 2—A HYPOTHETICAL COST AND SALES SUMMARY SHEET

in the departmental cost sheets through the use of the machine-hour rate.

Other statistical columns for each production order are machine-hours and man-hours. The special significance of these columns appears to best advantage in the periodic summary shown at the bottom of the Cost and Sales Summary sheet. In this summary the whole 6 months' operation is recapitulated and the stream of cost records meets the current of actual cost for the fiscal period. The first line shows the cost ledger estimates for all classes of expenses. The total estimated cost of all orders, for example, according to the cost ledger, were $13,500 for the period. This figure is to be compared with an actual cost figure taken from the ledger of $13,850, or an excess of actual over estimated cost of $350.

The estimated idle time cost is also seen to differ from the actual idle time charge. This discrepancy is due to the fact that the estimating figure was determined from the records of the previous period. A new index to be used next year will be calculated for each machine from the current departmental cost sheets.

The summary of machine-hours and man-hours is also significant. From the cost records the actual machine-hours are much less than the total factory hours. This figure of course is a part of the idle time problem and requires no further discussion. The difference in the man-hours obtained from the cost ledger and the actual labor hours obtained from the time clock is also a matter of interest. Naturally there will not be as many idle man-hours as idle machine-hours, but in all cases there will be a substantial number of labor hours which cannot be accounted for in the production records. This discrepancy is a total loss to the management. Naturally it cannot be expected that every man will work on productive labor the full operating time and if any man's record shows the full time the circumstance is sufficiently abnormal to justify a search for error. If the management cares to go into the detail, a continuous record or index may be kept of each group of men to determine how nearly the labor hours from the production records approach the full factory hours.

Other summary tables not shown here may be compiled from the "Departmental Cost Sheets" in which the efficiency of the plant for the current period is shown as compared with previous periods. When similar production orders are passing through the factory periodically, such as a given kind of paint, dye or heavy chemical, the current records set over against the records of last month and last year are important. The machine-hours and man-hours as well as the idle time charges per unit of product may be shown for each order for various fiscal periods. In short, a panorama of the year's operations may be presented by proper grouping of the essential facts in each period.

From the foregoing discussion it is apparent that a cost system, no matter how well devised, cannot increase the efficiency of the factory unless the management is willing and able to profit by the facts revealed by it. An X-ray photograph cannot mend an aching molar, but it is often indispensable in revealing the seat of the trouble. Cost methods are but one of the tools by which the management probes into the vitals of a business in order to discover the ailing members. The remedies, however, can be administered only by the master who is superior to any of his own methods or systems.

Washington, D. C.

Uniform Cost Systems

Uniform cost-accounting methods have been adopted by approximately 120 commodity lines, according to a survey completed not long ago by the fabricated production department of the Chamber of Commerce of the United States.

According to its report, forty lines have gone the whole distance in the adoption of uniform cost systems and in securing general use of them in their industries; approximately the same number have adopted complete uniform methods and are now facing the important problem of installing such systems, while the remainder have only worked out plans for simplification of accounts.

As shown by the survey, the following commodity lines are successfully using uniform cost methods: Steel barrels, malleable castings, cotton finishers, hosiery, west coast lumber, newsprint paper, printing, biscuit and cracker, portland cement, electrical contracting, knit goods, pressed steel, writing paper, wooden ware, caskets, chairs, envelopes, laundry, millwork, power piping and stoves.

Advantages to Manufacturers

A uniform cost system will give the manufacturer comparable results—that is to say, it will give him assurance that the other manufacturers in his line have included and excluded the same items into costs, that their enterprises have been substantially departmentalized in the same way as his own, that there exists a common treatment of overhead, a tying up of the financial and cost records, a control of raw materials. In other words, when the manufacturer studies his summary of manufacturing cost, he will be able to say that A, B and C are figuring their cost in the same way he is, and that any difference in costs is based on superior efficiency and not because of cost ignorance.

While making the survey, the department received scores of letters from trade associations and individual manufacturers pointing out the benefits of uniform cost accounting. Some of the advantages enumerated are:

1. It strengthens the position of industry in dealing with governmental or regulatory bodies.
2. It inspires confidence that selling prices are determined upon a fair and equitable basis.
3. It solves disputed points of accounting within the industry authoritatively.
4. It makes possible a more intelligent competition.
5. It reveals lines within the industry which have been marketed on an unprofitable basis.
6. It shows the danger line below which goods cannot be sold at a profit; thus serving as an insurer of profits.
7. It acts as a common guide to the value, efficiency and waste of workers, machines, methods, operations and plants.
8. It becomes a reliable guide and basis for estimating prospective business, thus acting as a forerunner for comprehensive production statistics.
9. It furnishes current reports for comparing major cost items with standards which are predetermined and thereby measuring and increasing operating efficiency.
10. It establishes a standard code of accounting practice, so that if your cost clerk or bookkeeper leaves you, his successor will step into a system whose operation has been fully and completely formulated.

In announcing the result of the investigation, the department let it be known that it stands ready to suggest the various means by which interest in cost methods can be aroused so that manufacturers will demand uniform cost accounting, rather than have it thrust upon them.

Some of the Effects of Labor Turnover on Production Efficiency

Lack of Harmonious Relations Between Employer and Employee Is Cited as the Most Serious Deterrent to Industrial Progress — Management's Problem Is to Maintain the Intimate Contact That Fosters Loyalty and Industry

By Philip Brasher,
Assistant to the President, Tide Water Oil Co.

EFFICIENCY of production has so many perils which beset it that ordinarily the more obvious of them are the only ones given consideration.

First of all, of course, in any organization there must be adequate financial equipment allowing the proper planning to be made and providing the necessary reserves of stock, spare parts and machinery. Operations must be so planned that no unit or component will be delayed by the lack of sufficient other components to make the complete assembled part. I well remember a factory in which I was called upon to inspect and improve production about 15 years ago. This concern was manufacturing hose couplings, and one of the first things that was called to my attention was the fact that the local manager considered that he was improving production efficiency by making up enormous numbers of one or the other components of the coupling, with the result that frequently for a considerable period it was not possible to ship complete couplings until sufficient parts of the other type could be made to fill the order.

Employer-Employee Relations

Most of us know what it is to be hampered financially and to have various and sundry setbacks in our plans, but really the most insidious, certainly the most vexatious and probably the greatest cause of delay in production efficiency is the lack of harmonious relations between employer and employee. The lack of harmony may be indicated in a number of ways, showing itself in the simplest form by excessive turnover, in a more aggravated form by various types of sabotage and reaching its climax in the form of complete cessation of work by strike or lockout. While I speak of the strike or lockout as the "climax," it is a very great question in the minds of those who have made a serious study of the subject whether or not the strike or lockout really results in as large a loss as excessive turnover. The effects of the strike or lockout are so very apparent compared with the insidious losses occasioned by turnover that they might well be likened to an acute type of disease like pneumonia or appendicitis compared with the wasting type of disease such as tuberculosis or cancer.

Breaking In the New Man

Unless an executive has come up from the ranks he can scarcely appreciate the delays occasioned by the constant employment of new men. The new man is, in 50 per cent of the cases at least, an inexperienced man and the foreman has the double duty of teaching the man his way around the shop and also his particular job. Of course, if the new employee is simply a pick and shovel man, he will not require a great deal of instruction but he probably will require an unusual amount of supervision. If, on the contrary, the new man is engaged in any kind of semi-skilled or skilled work, he will certainly need a great deal of both instruction and supervision. A foreman is but human and when he is busily engaged watching one unit of his outfit, it is manifestly impossible for him to pay the proper attention to the others, with the result that the work of a hundred men may suffer more or less while the foreman is concentrating his attention on the one.

As you go up the scale and employ a higher and higher type, the cost and the effect on production efficiency becomes more marked. Take, for instance, the case of employing a new foreman, and keep in mind that the foreman represents the management to the men. He is their real point of contact and no matter what your ideas and ideals are as head of your organization, unless your foremen understand and are in sympathy with them, your men will never know what you really are trying to do. It makes little difference for what reason the foreman previously occupying the position had to be replaced. He may have died, his work may have become unsatisfactory or he may have obtained a better position somewhere else. In any event, he probably knew his department. He unquestionably had certain men in whom he trusted and who were loyal to him. He most assuredly knew many things through experience that the new man will have to learn.

Loyalty, Intelligence and Industry

There are three outstanding attributes that any executive looks for in his subordinates. The greatest of these is loyalty, the second, intelligence, and the third, industry. No matter how industrious and intelligent a man may be, he is worse than useless if not loyal to his superiors. Therefore if the new foreman comes in from the outside, his job is first of all to ascertain the men in his department who are willing or able—and there is a very decided differentiation there—to be loyal to him. It is certain to take him some time before he can feel sure that he can depend on many of his subordinates. Until he reaches that point he can be of no great value in speeding up production because the men will be suspicious and possibly subconsciously hostile until they decide what type of man the new foreman is.

In order to illustrate the effects of the vicious circle caused by labor turnover, let me cite a specific case. A certain concern was manufacturing rifles for the British

Government. These rifles were inspected before acceptance by a corps of British inspectors, the head of which was presumably a younger son. The British were in great need of these rifles, but the rejections for trifling reasons increased to a point where it was almost impossible to get any of the rifles accepted at all. For example, a rifle which, under trench usage, would probably not last more than 4 weeks was rejected owing to a slight check in the stock which did not in any way affect the serviceability but merely the appearance of the stock.

The general manager of the company, probably not realizing the exact condition of affairs, called the production manager on the carpet and after a rather acrimonious discussion, a new production manager was needed. The new production manager, being a man of a great deal of force and very decided ideas, chose to begin his term of office by a very frank talk with the foremen of the various departments. This talk was forceful and probably effective with a number of them. It proved, however, a little too forceful for one of them who, on returning to his department, vented his displeasure on operative No. 594 who had charge of running five milling machines which performed operations 1 to 5 on the body of the rifle, there being a total of 157 operations on the component part. Operative No. 594 took the attitude that he was not going to have any foreman talk to him in that way and he quit, leaving a vacancy to be filled by the employment department.

Unfortunate Management All Around

This department, on receiving the requisition, employed John Jones, who represented himself as having been a machinist in the factory where a majority of the motor cars of the world are manufactured. The employment department, being very busy at the time, assumed that a man who had been a machinist anywhere would be capable of performing the semi-skilled work of running automatic machines and possibly did not realize that Mr. Jones' experience as a machinist had consisted in tightening certain nuts on the left hand rear wheel of the aforesaid car. Mr. Jones was escorted to the department where rifle bodies were being produced, the five machines were pointed out to him, he was given brief instructions and particular emphasis on the necessity for speed and was left to his own devices.

Until he had to replace one of the cutting tools all went very nicely, but when this became necessary, he unfortunately did not call upon a more experienced hand and attempted to fit the thing himself, with the result that every subsequent cut made was just deep enough to ruin the body completely and as there were over a hundred and fifty operations after this one, all of them were a complete loss and it was some time before the inspector in charge discovered the defective cut. By that time one-tenth of the production of that department for the day had been ruined. The foreman was notified and he very naturally interviewed Mr. Jones and gave him his opinion of his previous training and general character. Jones, being indignant, took it out on his machine and the gears were unable to stand the strain, two of them being smashed. One-tenth of the total production of rifles was thereby put out of commission for an indefinite period. Mr. Jones was invited to leave with dispatch and it became necessary to hire still another man.

As in all efficiently operated plants, the production of one department is ordinarily very much dependent on the production of the department immediately preceding it, and the loss of one-tenth of the production of this particular component was passed along down the line until every department was short at least one-tenth of its productive capacity. The foreman of the body department was called on the carpet with the result that he was discharged also. The resultant delay through all the departments eventually produced the release of the new production manager and so the circle became complete.

The release of the original production manager had worked itself down through the ranks and back up again with a loss of at least 10 per cent of production, two production managers, one foreman, two operatives and unquestionably others indirectly. In addition there was incredible damage to the morale, considerable expense incident to employing the new men, delay necessary to instruct these new men by their immediate superiors, breakage of tools and machinery by the new man and, finally, the spoiled work and decreased production which was inevitable under the circumstances. These are only the results directly traceable to the discharge of the original production manager and it would be impossible to estimate the indirect results. Any experienced man can easily guess how serious they were also.

Getting at the Essence of Industrial Relations

The whole question of proper industrial relationship has apparently won the reputation of being exceedingly difficult and complicated. As a matter of fact, in the writer's opinion, it is so extremely simple that it misleads many into elaborate explanations which do not explain.

Several years ago, while a certain country was engaged in a large war, the Secretary of Labor of that period decided to make a tour of the various industries in the country and give the executives in charge some valuable points on how their industries should be run. It is related that he arrived early one morning at a plant located far out in the middle of a desert, and presumably being hot and dry, the Secretary was not in the best of humor. He was met by the general manager, who expressed his desire to co-operate in every way, but the Secretary cut him short with a curt demand to see the grievance committee of the plant. He was informed that there was no grievance committee, upon which the Secretary burst forth with: "What? No grievance committee? I never heard of such a thing. It is outrageous. I can't imagine a plant without a grievance committee. Have a committee appointed at once to wait upon me at 3 o'clock this afternoon."

The manager went out to the plant, called his men together, stated the case to them and left them to appoint the committee. At 3 o'clock the committee waited upon the Secretary of Labor. "Well, gentlemen, what are your grievances?" said the Secretary. The chairman of the committee was an old Irishman and answering the Secretary of Labor, he said, "Sor, we have no grievances."

"What? No grievances? I never heard of such a thing. It is impossible. How do you account for it?"

"Sor, the manager of the plant, Mr. Coward, knows every man in the plant by name. He's in every part of the plant every day and if any one of us have any

grievances, we step right up to Mr. Coward and talk it out with him then and there. Sor, we have no grievances."

That story in addition to being true has the added merit of stating concretely the essence of industrial relations—contact. In my opinion, it is entirely possible for one man to manage and to keep in touch with a plant of 500 men. It may be possible, although I doubt it, for one man to keep in touch with and manage 1,000 men, but it has been demonstrated to be impossible time and again for any one man to keep in touch with more than 1,000 men if he has any other work to do.

There is a point of diminishing returns in the size of industrial organizations just as there is a point of diminishing returns in any other problem, economic or otherwise. I do not think it can be questioned that a number of our present-day organizations are too large for the men that control them. There are a few men in the country such as Mr. Schwab who can inspire an exceptionally large number of men with profound loyalty and consequently can handle exceptionally large organizations. In far too many cases, however, the executive at the top attempts to depend upon machine-like methods of control, leaving out the personal element entirely and thereby sacrificing the human interest and loyalty of his men. The result is inevitable—increased turnover and decreased production.

New York City, N. Y.

What Is a Living Wage?

In view of recent difficulties between railroad employer and employee there has been some talk of a movement in the Senate to amend the Cummins-Esch act in order to impose more clearly on the Railroad Labor Board the duty of assuring a "living wage." The provisions of the present law under which the board must act in labor disputes are as follows:

> In determining the justness and resonableness of such wages and salaries or working conditions the board shall, so far as applicable, take in to consideration among other relevant circumstances:
> (1) The scales of wages paid for similar kinds of work in other industries.
> (2) The relation between wages and the cost of living.
> (3) The hazards of the employment.
> (4) The training and skill required.
> (5) The degree of responsibility.
> (6) The character and regularity of the employment; and
> (7) Inequalities of increases in wages or of treatment, the result of previous wage orders or adjustments.

Discussing the language of this part of the law, Prof. Frank H. Dixon of Princeton, who is a specialist in transportation, has recently made the following statement, reproduced here from the August bulletin of the National City Bank of New York:

> No mathematical rule has been discovered for the determination of a reasonable wage. But so long as we maintain our régime of private industry, one of the determining influences that must be accepted by any wage-adjustment board is the first-named of the seven conditions listed in the statute, "the scale of wages paid for similar kinds of work in other industries." Granted that the statistics of wages have been honestly and intelligently gathered and that no manipulation of wage rates has occurred through undue pressure of combined capital, the price that must be paid for similar labor in the open market is one of the conclusive factors in determining the reasonableness of a prevailing wage standard. Moreover, in connection therewith the board should adjust wages in harmony with the industrial conditions of each locality. Standardized wages effective over wide areas can with difficulty be defended on any economic basis. Their reason for existence is political and strategic. Testimony submitted by the employees themselves in Chicago recently is a virtual recognition of the need of restoring those differentials between town and city and between one section and another that were largely destroyed during the period of the national agreements.

The provisions of the law seem to be comprehensive and reasonable. It is right that conditions peculiar to railroad service should be taken into account, but there is no justification for setting up a special standard of living for railroad employees. The conclusive reason against it is that other people, many of whom have a lower standard of living, would have to pay the bill.

Standards of Efficiency of American Labor

The much-discussed question of the efficiency of American labor, particularly in comparison with the standards of output which prevailed prior to the war, is the subject of a recent article in the *Monthly Labor Review*, contributed by Ethelbert Stewart, U. S. Commissioner of Labor Statistics. Mr. Stewart shows that the basis for much of the current belief that the American workman is not as efficient now as formerly is found in general statements which have no backing of statistical proof. Against this state of affairs he presents considerable data from particular industries showing that a proper consideration of all the elements entering into production does not evidence a general slackening of effort on the part of the workers, but in a number of industries increased efficiency is shown. Mr. Stewart urges the need of time-cost studies as a basis for scientific measurement of labor efficiency, not with a view to "speeding up" industry but for the purpose of establishing a definite standard for judging work.

In connection with the subject of labor efficiency, a review of a recent speech by a prominent coal operator shows the excessive amount of "idle-day costs" in the coal mining industry because of the overdevelopment of the industry which results in the non-operation of many of the bituminous coal mines of the country for a large proportion of each year. The total annual loss to capital and labor because of the closing of the mines for approximately 100 days each year is estimated at more than $400,000,000, more than three-fifths of which represents lost wages. Moreover, no consideration at all is given in this figure to the loss to the general public of the productive effort of this large aggregation of men for about one-third of the working year.

The Industrial Physician

That the introduction of the physician into the industrial organization, often made during periods of stress or to comply with legislative enactments, has produced many interesting and beneficial results is the conclusion reached in a report issued by the National Industrial Conference Board, for the Conference Board of Physicians in Industry, which acts as adviser to the National Industrial Conference Board on industrial medical problems. The physician's work in the organization has revealed to the employer many sources of economic waste and to the worker the unnecessary price he is paying for inattention to his health and the health of the family; while to the physician himself has been given a broader view of the value of his services in creating and maintaining better living and working conditions.

The Increasing Importance of Research Demands That It Be Placed Upon a Stable Foundation, Not Subject to Fluctuations of Business Nor the Whims of a Non-Technical Executive — Creative Research Is Otherwise Impossible

The Relation of Research To Production Efficiency

By C. G. Derick

CAN you picture a vehicle making progress whose wheels have no hubs? A modern chemical business without a research organization is making about the same rate of progress. The recent period has been an exceptional opportunity to witness the collapse of business vehicles lacking this hub.

You can picture a vehicle making some progress on the hubs. They will turn over, they will decrease friction. Research organizations can be made self-supporting by the sale of their products manufactured during the developmental stage.

But how much more efficient is the vehicle when the hub is drawing support from the tire and the rim through its spokes. Efficiency is at its maximum: friction is reduced to a minimum. No business is operating at its maximum efficiency if the sales department tire is not properly supported by the operating department rim and these properly connected through the spokes of co-operation with the research hub.

The research hub must firmly surround the axle of finance. A perfect understanding and belief in each other must lubricate the two, while a spirit of service to mankind must drive the whole business vehicle.

In any large industry it requires 5 to 10 years to develop a proper research organization. Unfortunately, it requires a decision of a few seconds to wreck it completely. The form may remain to decay slowly after the spirit of accomplishment has departed. The spirit of a research organization is the difficult motive power that requires years to develop, and all the accomplishments of such an organization hinge upon this spirit. Given the correct type of men possessing the research spirit, years are required to familiarize them with the details of the particular business and to weld them into a co-operative unit of production.

Research Should Not Vary With Business Fluctuation

The research organization is the incubator of all lines of future development of a particular business. For this reason a carefully selected group of men must be left absolutely free to explore in all branches of science that are in any way connected with the industry. These men must have the necessary equipment and surroundings to accomplish their tasks and be guaranteed a permanency by a proper mode of financing that is independent of the fluctuations of business. Indeed, this is true to a lesser degree of the entire research organization, but on the developmental side of the research organization expenses may usually be more closely synchronized with business conditions. The exploratory side of a research organization can absorb limitless amounts of money and usually the results will be directly proportional to the investment when the organization has been properly developed. These facts demand the definite financial policy of creating a fund—yes, an endowment—to carry on this work which is properly balanced against the average earning power of the particular business.

The developmental side of a properly balanced research organization does not, except by accident, create new processes or make fundamental discoveries. It furnishes the machinery for developing into efficient *commercial* processes the useful results of the exploratory side. It can be made self-supporting. It can and should be subjected to correct methods of business control. It should become the training school for plant operators, salesmen, accountants, executives, etc. It must be properly housed and in large organizations have its separate manufacturing buildings where experimental results may be tested out on a commercial scale. It must not interfere with production, it must accelerate production. In other words, it should be a small model of the complete business. In no department of a large industry can the spirit of the industry be taught so quickly. Consider the enthusiasm and intelligence of a staff which had grown up with the processes as they had developed. This condition must exist in the not distant future if we are to meet competition.

The Research Organization

A research organization must be further divided into small groups responsible for the different functions of the laboratory. For example, the exploratory side must be divided into groups centering about strong personalities and the developmental side into the groups—business (including accountancy), research chemical engineering, research operating, chemical (doing the actual research of development), library (controlling scientific and business literature, patents, etc.), research analytical, etc.

The co-ordination of the various groups of such a research department is best brought about by the conference system. Most of the groups should hold regular weekly conferences with a secretary present who records the discussions and conclusions. Concise minutes of these conferences should be placed in the hands of each important member of the group and each of the other group leaders. These group leaders and designated members of their group should be free to attend the conferences of any other group. In this manner the freest interchange of ideas and information is obtained.

When a laboratory process which has business possibilities has been developed by any of the exploration groups, a member of this group may be transferred temporarily or permanently to the chemical development group that will perfect the process and the connecting link be established. The attack of the problem having been thoroughly developed in conferences and the developmental work completed in the laboratory, a process write-up with recommendation as to suitable manufac-

turing apparatus is forwarded to the research engineering group, which draws up a report determining the necessary equipment and locations for experimental manufacture, including a complete cost estimate of the installation. These two reports are forwarded to the research operating group, which determines the material, labor and general operating costs for the manufacture of sufficient batches of products to establish proper operating procedure and costs. The three reports are returned to the chemical development group for comments. In case of disapproval of any report by any group, the difficulties are settled in conference. When final agreement is reached, the research engineering group installs and tests the equipment and the research operating group carries out the operation under the advice of the developmental chemist.

Careful cost accounting is maintained throughout the exploratory and developmental stages. Proper credits are given this expense for the sale of products made during the experimental manufacturing period.

Before the process is established upon a commercial scale, the sales department should have already probed the market for the product with the production of the research department, and now must establish an intelligent sales program. Upon the basis of this program the plant operating and the research chemical engineers lay out the finished plant. With proper executive approval the plant is erected and operated during a test period by the research operating department and when operating normally the research department withdraws, leaving a former member and trained operators in charge of the operations.

In a similar manner members of the research department are transferred to sales, engineering, accountancy, executive, etc., departments and gradually the business is operated by men with a comprehensive conception of the entire business and the requisite sympathy through understanding to force success. Thus the spokes of coordination are developed and the wheel is ready to roll.

Technically Trained Men as Executives!

This is no idle dream. There are organizations in existence built more or less upon this plan. It if takes 5 to 6 years to build a proper research department, other departments are being built simultaneously, drawing the backbone of their organization from the research department during this time. So at the end of the period a complete business structure has been erected.

Is it too much to hope for accountants in chemical industry who are graduates of chemical courses? Is it too much to expect librarians in chemical industry to be graduates of chemical courses? The writer found little difficulty in obtaining such men. And how fast the plant accountants were to draw such men from the research department!

Is it too much to hope that all chemical industry may be directed by executives with chemical training and financed by financiers with chemical training? The conspicuous success of the few daring chemists who have tried these fields is just an indication of the future. The universities must aid in this and the professors of chemistry must stop impressing upon the formative minds of the young chemists that it is degrading to leave the direct paths of chemistry for those of business based upon chemistry. A noble success is the greatest reward of the teacher no matter in what line his students make that success.

The research manager must be a member of the board of directors, as must all of the main heads of the business. He must be more than a consultant, he must have a vote. The financial interests must not monopolize these boards. It is not enough that the members of the board of directors may have had a chemical training, it must include the active chemical and engineering and sales leaders of the particular business. Such a directorate can properly serve its stockholders. The present unrest beween labor and capital would find in such an organizaion one less cause for discontent.

Business Wrecks From Neglect of Technical Man

Of course, most business has been built up around some research, but usually a production and a sales department have been organized and operated long before a research department has been established. It is a peculiar fact that money can be readily obtained to float new enterprises upon someone's say-so that there is a profit in the business. A beautiful prospectus extols the charms, but a critical study of the same by a research expert usually reveals not a single concrete bit of evidence for the claims. When, however, he suggests that the financial interest expend a few thousand dollars to test out the claims, the atmosphere becomes chilly. After an enormous expenditure of money there is built up a business that faces bankruptcy in a crisis. Then the expert is called in. He states that the business is economically sound and that such a sum is needed to work out an efficient process. He does not get it, but may get sufficient to make a start. He tries to repair a broken down machine. He pleads for money to make a complete investigation of all possible competing processes. He does not get it. But if he is financially strong enough, his love of a properly completed job forces him to finance these additional investigations. At a cost only a small fraction of that already spent in process development in the pot-boiling fashion of the plant he determines a new process operating at a fraction of the cost of the going process. Step by step he develops his work to a manufacturing scale. The old process is abandoned and the new process makes a small income on an enormously excessive capitalization. Due to the unwillingness to invesigate thoroughly before attempting manufacturing, a return of 3 per cent during bad business years is obtained instead of 15 to 20 per cent. Industry is burdened with such cases.

Again, a financial executive scorns the opinion of his research and other advisers in the actual work, and he purchases a process. He cannot purchase a trained personnel to operate it under local conditions. In a few months a million dollars has suddenly disappeared from the business. Then the research staff is forced to develop the same product and the business to carry this additional load. Another group of executives swollen by their own importance desires to operate a number of plants which the technical members of the company insist are unnecessary, and in a couple of years several millions of dollars have disappeared. Ultimately through necessity the technical adviser's opinion has to be followed, often after bankruptcy has given control to others and the public has paid the bill.

Again, an organization with a few broken spokes finds an individual who thinks he has arrived and to feather his own nest prevents the results of his experts being turned into marketable products because of some pet products of his own. Millions of dollars are lost.

A sympathetic organization built about a research department could often prevent and usually greatly decrease such losses. The interest on the money squandered by many firms in this manner would support enormous research organizations indefinitely.

Another phase difficult to understand and fatal to efficient research is partly illustrated by the last example. It is more common than is usually admitted that large organizations often prevent the marketing of superior products that their organizations have developed. They put them on the shelves until competition forces their use. They argue that the cost of junking old equipment justifies the end. There is no excuse for doing a thing in a less efficient manner than is known. But the deadening effect of such a policy upon the spirit of a research organization is beyond human ability to estimate.

The Remedy

In what directions can we look for relief from such conditions? Educate the business public to insist upon a research report before investment. A difficult problem! Educate the chemical professor that his students need the principles of economics and business as well as chemistry and physics and that he should not give special courses in cement analysis because John Jones has a cement mill in the neighborhood and will pay his recent graduates over a hundred dollars a month upon graduation. He won't tell the trusting professor that that is all the student will ever get unless the latter makes a good fight. Educate the chemist that if he is to be anything but a glorified laborer he must be willing to enter business like the lawyer, the physician, the dentist and the untaught business man by financing himself at the start and to expect a few lean years. Of course all chemists will not build a successful business of their own, but enough seed will fall into fertile ground to cause scientific business built about research organizations to develop and drive out the inefficient and unscrupulous.

Buffalo, N. Y.

Editor's Note: The subject which Dr. Derick has so ably presented is one which we believe to be of vital importance. Dr. Derick's apt simile that a modern chemical organization without a research department is like a vehicle whose wheels have no hubs is grimly accurate. Yet in spite of the obvious truth, chemical organizations in the interest of a false economy have dispensed with their research organizations during the last few years of stress. This statement can almost be made general, so widespread was the elimination of research men.

Should the Dyestuff Industry Die?

Let us be specific for purposes of illustration. Manufacturers of dyestuffs developed during the war large research organizations. It is an essential in this industry so obvious that even the capitalists recognized it. But at the first sign of depression the old cry was raised—"Where can we cut? We must maintain only that force necessary for minimum operations." Research is not necessary for minimum operations, and so research must go! The ultimate result is inevitable. Instead of being an alert organization, strong in its own right, progressive, welcoming competition because it is ready to meet it, we find a fearsome spirit born. Germany will swamp us. We must have protection, embargo. Foreign patents must be worked in this country or licensed to people who will work them. That this is unnecessary is evidenced by one courageous firm which has been able to sell in Germany. What the dyestuff men need most is not protection or embargo or patent rights—all of these things tend to pamper and nourish the industry artificially—but an infusion of some of the pioneer spirit which will establish confidence in research and a realization that by and through research the industry must emancipate itself or die.

Ready Made or Made to Order

Heavy chemical manufacturers have felt that their processes were so standardized that "fundamental research" was foolish and a waste of time. And yet they have been paying tribute money to those research men who developed contact sulphuric acid, and now synthetic ammonia. Why will they not realize that it is healthier, cheaper, better for the country and themselves in general to invest in research rather than buy it?

Some industries have courage and vision. It is a heartening thing to hear of the establishment of a large research department by the Standard Oil Company of Indiana. Some of the most promising young talent in America will go to it. Our prediction is a foregone conclusion that the Standard Oil Company of Indiana will never be worried by foreign competition, will not have to lobby for protection or embargo even if the Russian oil fields should be run for nothing a month and the American oil fields simultaneously evaporate.

Corporations can now talk about economic inequality and a thousand other misfortunes which militate against them, but some day the public will be convinced that the pinch-penny methods of saving the immediate dollar (which after all is the real reason for no research) is too expensive for it and it will not tolerate a pampering of industrial sloths.

This must not be interpreted to mean that we are not in sympathy with a tariff. But a tariff which protects a growing young industry is a very different thing from a tariff which removes all need for progressive effort and amounts in the end to a tax on the general public for the manufacturer's benefit. Tariff should be a spur to action, a stimulant to progressive effort, and not a narcotic which lulls the manufacturer to a comfortable somnolence and without which he wakes to a whining plea that he cannot live without it.

Co-operation Pays Dividends

There is still another idea which seems to go hand in hand with research and increased production efficiency. It is co-operation. Not long ago a young chemical engineer told us that in his work he had been associated with three separate acid manufacturers. Each surrounded his plant with so much secrecy that practically no one except the men directly connected with each unit knew anything about operation and yields. The operating flaws in one plant were corrected in another and vice versa. The thought which struck this young engineer was, "If they only would pool their knowledge, all of them would be better off." It is so in metallurgical work. A competitor is invariably a welcome guest and metallurgy is an outstanding star in American industries for efficiency and progressiveness. Perhaps it will be the millennium before chemical manufacturers arrive at that same point. Perhaps it won't. For the sake of the industry speed the day!

The Business Cycle as a Factor In Production Efficiency

A Study of the Recurrent Ebb and Flow of Business Activity Reveals Many Practical Ways in Which the Individual Executive Can Forestall the Disastrous Effects of an Industrial Crisis and Depression

By Ernest T. Trigg,
Vice-President, John Lucas & Co.

AN OBSERVANT MAN can scarcely pick up a newspaper or magazine nowadays without seeing the term "business cycle." It has been receiving considerable attention in recent months, especially after President Harding's Conference on Unemployment appointed a subcommittee to study its causes and effects. Many have called such a study "highbrow" and have dismissed it with a contemptuous shrug and perhaps the comment that it was something for college professors to play with, but of no serious consequence to the business man.

But it is the opinion of the writer that it is of vast importance to the business world of the United States—this study of the business cycle. Is the country helpless to prevent it? Have we got to have good times and bad times every so often, willy-nilly? Is there no solution to this problem?

But before attempting to solve such a difficult problem, let us look to the term itself: What is this so-called "business cycle?" Briefly, it is that recurring process of booms and slumps that affects our industry and our business directly, and our agriculture indirectly. Obviously the solution is to lop off from the peak in boom times to fill up the trough in depressions—in other words, to temper an industrial crisis by acting before the crisis becomes inevitable. The idea, then, is to plan for the future by applying a knowledge of the past.

Let me quote from a document which came before the recent conference:

> The vast majority of the unemployed were recently on the payrolls of private business enterprises. These men lost their jobs because their employers were losing money. Over 15,000 business enterprises have been forced into bankruptcy since the present period of depression began, and the number now operating at a loss must be very large. Unemployment on a vast scale is always a result of business depression. The problem of preventing or mitigating unemployment is therefore part of the larger problem of preventing or mitigating alternations of business activity and stagnation.
>
> Such alternations have been a prominent feature of business experience for a century or more not only in the United States but also in all other countries that have attained a high state of commercial organization.

Careful Planning During the Upward Swing

> The business cycle is marked by peak periods of boom between valleys of depression and unemployment. The peak periods of boom are times of speculation, overexpansion, extravagance in living, relaxation in effort, wasteful expenditure in industry and commerce, with consequent destruction of capital. The valleys are marked by business stagnation, unemployment and suffering. Both of these extremes are vicious, and the vices of the one beget the vices of the other. It is the wastes, the miscalculations and the maladjustments grown rampant during booms that make inevitable the painful process of liquidation. The most hopeful way to check the losses and misery of depression is therefore to check the feverish extremes of "prosperity." The best time to act is at a fairly early stage in the growth of the boom.

Business is improving. Times are better. But that is not enough. Business must continue to improve and in hundreds of offices today business men are sitting down and trying to figure out how to maintain the increase in their business that has started.

In the past 20 years we have had five business slumps. Things were dull in 1903; there was a depression in 1904; improvement in 1905; boom in 1906-07; depression in 1908; activity in 1909-10; a minor crisis in 1911; a gain again in 1912-13; a depression in 1913-14; improvement in 1915; uncertainty in early 1916; then the war boom, interrupted after the armistice, 1918-19; then the post-war boom, and finally the depression of 1921. How are we going to make such periods more even—that is, take something off the top of the booms and fill it in the troughs of the depression?

The Work of the President's Committee

The standing committee of the President's Unemployment Conference is trying to answer that question. A subcommittee has been appointed. Owen D. Young of New York, vice-president of the General Electric Co., is chairman, and with him are Clarence Mott Wooley, Detroit; Joseph H. Defrees, Chicago; Matthew Woll, Chicago, and Miss Mary Van Kleeck, New York. The survey of the business cycle has been undertaken by the National Bureau of Economic Research, Inc., of New York, of which Dr. Wesley C. Mitchell, the American authority on the business cycle, is director.

Among other proposals for stabilizing employment, it will take up long-range planning of public works and of construction and maintenance work by private employers; unemployment insurance and unemployment prevention by governmental agencies; depression insurance by private employers; employment offices, public and private; out-of-work benefits by labor organizations; financial devices for controlling the business cycle; and improvement of statistical indices of employment and other "business barometers."

These recurring periods of inflation and deflation in general business are intimately reflected in each individual business, and each individual needs now to study his own business cycle. The organizations which have done this in the past have reaped prompt benefits. Some of these are the Dennison Manufacturing Co., the American Radiator Co., and the American Telephone & Telegraph Co., and a rapid survey of American business shows more than fifty other examples of intelligent anticipation of the business cycle by American business men.

It is worth noting that this intelligent anticipation results not merely in greater security on the job for the employees—and of course the President's Conference on Unemployment is interested in that—but also it has resulted in profits to the employer and work for the

worker, at a time when other people's business was in the doldrums.

There was a time when the country had a financial panic about every so often, precisely as it now has the business depression. But the Federal Reserve system has taken away this threat of financial cataclysm. And so we ask, Why not something to fit the business cycle as well? Secretary Hoover feels exactly that way and he hopes to find the answer by the study in which the committee is engaged.

The Seasonal Slumps

But these larger movements of booms and slumps are not the whole story. In every year comes the minor problem of seasonal intermittency and unemployment. Generally speaking, the summer months, with their slackening of activity, and the vacations, which interrupt the flow of business, are followed by the busy autumn period; after the rush of the holidays comes another dull season.

Particularly building, of course, slows down in winter; manufacturers of agricultural implements have their maximum number of employees in the late winter; automobile building falls off in the autumn. Hosiery, garments, shoes, have two peaks of employment a year—early spring and autumn. Twice as many factory workers are idle in Massachusetts and New York State, for example, at the end of March as at the end of September of the same year. We all know that there is an off-season on the farm after the crops have been gathered and the fruit picked. Road building slows down in winter, and logging camps are idle in summer. The fisheries fall off during certain seasons and so it goes.

Just as some business men have controlled the cycle of their own affairs, so these seasonal waves admit of control within certain limits. How far this policy can be carried by the industrial business man cannot be ascertained until he tries it with his own business. Anticipation of demand, analysis of markets, extra sales effort—all these have been used with surprising success.

Application to the Individual's Business

The important point to realize is that unless the American business man has studied his business over a period of many years and is laying his plans accordingly, he is missing something this year and by that much is the helpless victim of so-called "blind economic laws." Working together, American business men, manufacturers and farmers can do even more. They can deal not only with the management inside their own particular industry but with some of the forces which affect them from the outside. Right here is where the study of unemployment and business cycles may be depended upon to increase the year-around efficiency of production. Already the value of organized effort in modifying the evils of booms as well as of slumps is very clear.

For example, the policy of holding back construction work in boom periods and of expanding plans and equipment in dull ones will enable the business man to take advantage of lower costs at the right time. He will not be paying high prices for material and labor in boom periods by overbidding his competitor. In other words, the business man will not throw away his money in good times, but will set aside a portion of it to keep the industrial wheels going in the off-years, thus creating employment for more men and a demand for more goods.

On the other hand, every mistake in judgment by those responsible for commercial and industrial decisions results in waste. In the year 1921 alone, 19,652 manufacturing and trading companies went into bankruptcy, with liabilities totaling over $627,000,000 and with thousands thrown out of work. Practically every one of these failures was the result of mistakes in judgment. Thousands of other business firms also made mistakes, which resulted in a waste of capital, material and resources and unemployment, but for one reason or another they have not been forced into bankruptcy. The elimination of this waste of capital and resources which is continually going on is one of the big problems of today.

Support and Co-operation Needed

Preliminary surveys already made by the Committee on the Business Cycle clearly indicate that there are many practical constructive measures for stabilizing production and mitigating off-years. Statements of theory and principle are of little value unless they are worked out so that they may be applied to actual business. And that is just what the President's Conference on Unemployment wishes to bring about—to show to the business men and employers of the United States that they have in themselves the power to ward off the business cycle completely, or else so to mitigate its evil effects that only a little self-denial and prudence will enable everyone to carry on until the turn of the business tide. Sound thinking and intelligent planning can largely control the cycles of depression by forecasting the course of business. But how can this forecasting be done? By the use of statistical material placed at the disposal of business men by the government. That is what should be given the industry of this country. If the business men of the United States will give this committee enough leads in successful experiences in stabilizing production and in long-range planning of construction, the way will be found out of the difficulties of the business cycles. Secretary Hoover says:

> The President's Conference on Unemployment has been hampered in its work by lack of definite knowledge concerning the extent of enforced idleness in the United States.
>
> The defects of present unemployment statistics are due to the fact that government departments and other agencies cannot now obtain regular, comprehensive and authenticated information from industry and commerce.

What Secretary Hoover says on the lack of employment statistics is even more painfully apparent concerning the other phases of industry. Present figures on production and consumption are utterly inadequate. They do not cover the field; they do not bring to one business what is going on in another. Such a knowledge is possessed by the few today, but if present plans work out it will be the property of the many.

The business cycle has been for centuries a world-wide industrial problem; a dismal economic phenomenon too long endured by civilization. For the first time in history an organized attempt is being made to overcome it. If it can be done, the credit should go to American inventiveness and persistence.

Philadelphia, Pa.

The Importance of Scientific Control in Increased Production Efficiency

An Analysis of the Reasons for the Comparative Neglect of Scientific Control — A Study of Its Technique — An Estimate of Its Advantages—The "Sine Qua Non" of Increased Production Efficiency

By Charles H. MacDowell
President,. Armour Fertilizer Works

OUR first industries were located with reference to available supplies and easy transportation to consuming centers. We used our richest and most accessible raw materials. As labor cost was our greatest concern, we developed labor-saving machinery, and as capital became more available, we adopted large unit and standardized repetition methods. As our supply of technically trained men was limited and as our pioneer experience had developed an ability to simplify and extemporize, our lumbering, mining and manufacturing growth proceeded along practical, hard-headed lines. We laid great stress on immediate costs, with but little regard for the future or for making the most out of what we had in hand. An inspection of the tailings and slag piles of the past shows how crude and "main strength" we were in our methods in mining and metallurgy.

As we worked out our most available supplies and as demand for finished products increased, we went further back into the woods and hills for our materials or increased our purchases of foreign water-borne crude products. We still specialized on the mechanical side. In metallurgy, especially in copper and precious metal recovery, the need for cunning as well as main strength was appreciated earlier than in many other lines, and technical advice was sought and utilized. Other industries have followed in a way and the technologist is now having his day. We are still too much inclined to worship exclusively at the shrine of the "practical" and "self-made," and do not yet fully appreciate that the "know why" adds to the "know how" in arriving at the "how much."

Scientific control in manufacturing begins at the bottom and starts at the top—speaking in a Gaelic manner. If those in top control don't start it, the ones at the other end don't do it. It follows, therefore, that the head executive must appreciate its need and get it under way, and there's the rub—he is the fellow who must be shown. He pitches the tune, he is responsible for results, for the selection of his colleagues, for their ability, capacity, willingness, his breadth and vision is their breadth and vision, his grasp theirs.

Control in Industry Analogous to Orchestra Control

Control is positive in principle and is based on mental, moral or physical characteristics. One of the highest types of control is exercised by the leader of a great orchestra. The individual musicians are thoroughly skilled in the technique of their art and have mastered their individual instrument, and yet must accept the positive control of their leader if the orchestra as a whole is successful. The leader must be able to obtain the hearty co-operation of all members of his organization. He need not necessarily be an expert with a single instrument in the orchestra, but he must know and understand not only the possibilities of each instrument and performer but he must know the effects that may be obtained with the co-operation and combination of the various instruments.

The leader of an industry has the same problems to solve as has the leader of the orchestra. He must surround himself by skilled men capable of the fullest co-operation. They must be as competent to receive direction as to give it. The leader sets the pace and on his ability, capacity, intelligence, breadth of vision, positiveness of decision and general friendliness rests the success or failure of the undertaking. Those whom he leads, those to whom a portion of his responsibilities are delegated, must be under his control, and these men, in turn, must control the actions and operations of their subordinates.

More Advanced Control Methods in Europe Than in America

Manufacturers in Europe, working with comparatively small units and competing for world's business, have been compelled through necessity to maintain a closer day-to-day control of their manufacturing than have many American manufacturers. Our genius has run along the lines of repetition, obtaining our efficiency largely through mechanical means. We have had our home markets to supply. Our buyers were willing to accept standardized products and our greatest industrial successes have come through supplying these. Because American payroll rates are high, we have often placed the type of man in control of our plant management who could best speed up labor handling, who thought out large unit methods of handling to get economies in labor. In many instances such men have not appreciated the fact that there were other elements of cost which might be reduced, through closer study of yields and quality, inspection of incoming materials and the greatest possible utilization of raw materials purchased or manufactured. The time is now here when we must study more closely the control of our manufacturing processes from the scientific and engineering standpoint. Many of our industries are doing this now. In order to bring this about, those in charge of manufacturing must thoroughly appreciate the need of using the scientifically trained man in carrying on actual production in the plant. Such a man today is too often kept in the laboratory, in the office or in the machine shop.

Some of the Technique of Control

Efficient control starts by knowing what you are buying; whether what you buy is best suited for your purposes, and that the specifications on which purchases are made insure such deliveries; by seeing that material is carefully weighed and inspected when it comes into the plant and that shrinkages in handling are known and figured into cost. The ultimate cost of raw materials is fixed by the amount of finished product a

given quantity will make. The original cost may be no measure of final cost. Material that has to be culled before using has added to its cost not only the rejected goods (for which credit may be received) but there is a labor cost and a loss of time, all of which affects costs. Shrinkages are often ignored in factory cost accounting, yet in some industries this item amounts to a very considerable percentage of the raw material cost. Careful inspection of all scales and other measuring or testing devices is necessary to keep them in efficient condition and, what is more, a continuous inspection of the work of the men who are handling these devices to eliminate, as far as possible, carelessness or spite work errors which so often creep into plant handling. Without control, there would be little inspection of machinery, with many breakdowns resulting.

Rigid Inspection by Trained Men

Efficiency in this department comes in such rigid inspection by trained men that the worn parts are always replaced before they break and at times when the machine can best be idle without curtailing output. A mild form of sabotage is not uncommon among present-day labor, in allowing a machine to break down with a resulting rest for all hands rather than reporting its condition so that it might be fixed in time. Efficiency is furthered by good housekeeping, so that from day to day materials are kept clean, in their proper places and uncontaminated, as far as possible, from admixtures with other materials. An intimate knowledge of the composition of each incoming shipment, that the greatest yield may be obtained from that particular consignment, is also necessary. Concise, up-to-the-minute reports of the result of the day's work are needed by the superintendent that he may avoid hidden losses and correct any errors which may have crept into the day's operations. A careful study of what is the largest practical unit to handle a given material is necessary. It sometimes happens that hidden losses result from too large operations more than offsetting the labor gains coming from handling the larger unit. An immense amount of capital may be invested in machinery for a certain operation. The interest charges and depreciation can be charged only against the output of that unit. If its capacity is greater than necessary, it may often stand idle and the operation cost per unit be increased to a point where the job might have been done by simpler methods at a cheaper cost. Machinery operating costs cannot be figured by the job, day or week, but the year's cost must be borne by the total output. It may well be that the greatest economies are lost from treating materials in too small batches, that too much labor is used and unnecessary motions made.

Study of Cost of Multiplication of Grades Essential

The factory makes what the sales force calls for. Careful study of the cost of multiplication of grades on the part of the factory and a forceful report to the sales end as to what these diversions cost in plant operation may result in economies to the business through a better understanding on the part of the distributing organization of the effect of this kind of salesmanship.

We might go on at some length detailing these causes of financial loss, which we all know but of which we so frequently do not appreciate the importance.

Far too many of our plant and department superintendents do not yet comprehend how the prosperity of their companies can be augmented by a greater use of scientifically trained men—men from the technical high and manual training schools as well as from the universities. They are too prone to relegate the chemist to the laboratory and to keep the engineer bent over his drawing board, considering both necessary evils. They are overlooking the fact that these men can frequently be made efficient operating men, helpful in every way to a better handling of plant product. Men trained to analyze, synthesize and properly handle can become of great value to any concern manufacturing intermediate or finished products from raw materials. In order that proper manufacturing control can be exercised by the executives, they must have placed before them periodically a correct cost analysis of the business. Such work must be handled by scientific cost accountants. If it be not accurate it is practically worthless. Each operation must bear its proper proportion of all expense. Adequate depreciation must be charged so that the cost of any machine or even factory will have been written off when it is necessary to renew it or it becomes obsolete. Only by such accounting is the factory executive able to discover unprofitable operations so that he may eliminate them or revolutionize them, till their cost is not excessive. The plant accountant thus becomes a very important factor in scientific control. An organization built up in part and run in part by such men cannot but know daily where it stands, can avoid hidden losses and can carry on a scientific control of its operations which should give it a decided advantage over competitive companies not similarly organized.

Do it right today—post mortems are often unpleasant.

Hearty Support by All Is Necessary

In furthering a scientific control it must be fully appreciated that it must be heartily supported down the line, that each department head, foreman and subforeman must know why a certain method is to be followed and be in sympathy with the end sought. He must be kept in a constructive as well as an executive frame of mind that improvements in methods may follow and that he may have opportunity for advancement. The personal side of control is all important.

A leading French official, during the peace negotiations in Paris, ventured the opinion that the greatest loss which had come to Europe as a result of the World War was the loss of command. He believed that, as a consequence, Europe would suffer severely for many years. He had in mind the losses from death and disablement of so many men who were mentally and morally capable of sound thinking and of leadership. He also had in mind the disinclination of many of the rank and file to submit to the discipline necessary to carry on in an orderly way the methods necessary for efficient creation of new wealth. The man with whom I was talking was a liberal in politics, experienced in production and a far-seeing, clear-thinking man.

The attitude of the executive toward those with whom he is associated—superintendents, foremen and workers—have much to do with securing control. Control is essential in the working out of any project.

Scientific, carefully studied, humanized control is necessary if the world is to solve its present problems.

Chicago, Ill.

The Modern Chemical Plant

The Successful Conduct of Industry Today Depends on Good Plant Engineering—Plant Engineering Begins When the Plant Is Designed—The Factors Which Must Be Taken Into Account Are: Location, Layout, Design, Construction and Equipment

By Frank D. Chase
President, Frank D. Chase, Inc., Engineers and Architects

SOME DAY someone will write "The History of an American Industry," and the reader and student thereof will learn some valuable lessons applicable to his own business.

The chemical and allied industries are comparatively unexpanded, although not new; but through the lessons of other industries many manufacturers are going to profit, not only by their own mistakes and those of their competitors, but by the history of other lines of manufacture.

The chemical industry is going to follow other American industries through a period of radical evolution. Nearly every manufacturer, regardless of his product, recognizes this; and the more progressive and far and clear thinking men not only recognize this fact but understand just what this is and what it means to them.

To continue in business, to exist as a going concern, one must meet this revolutionary situation and master it.

Success in Past Due to Horse Sense and Hard Work

For generations American manufacturers have prospered and expanded, and it has not been extremely difficult to do so. The markets for products have grown faster in scores of instances than the manufacturer could supply. Raw material and labor were abundant and cheap. Competition was usually negligible. Horse sense and hard work counted about 99 per cent.

All this is changed. Raw material prices are usually controlled by interests powerful enough to dictate prices. Labor is paid more, is organized and demands, deserves and is receiving more than in the past. Advertising is a necessity. Competition is keen—new plants, some small, many with large capital, are entering the field. Scientific management, in two words, is the summation of this radical revolution.

The Modern Role of Plant Engineering

While horse sense and hard work still bulk large in the successful business—in fact, no business prospers without them—there is one more factor to be taken into account in modern business. This factor is science. We all know that the chemical factory would not function long without the laboratory. This is science. The chemists have developed materials, processes and equipment which can be used only with a knowledge of chemistry. This is science. Your raw materials and your process and finished product are dependent upon chemistry. This is science. There is one other branch of science which is today recognized in almost every industry in this country. I refer to plant engineering, as playing an essential and increasingly necessary part in not only the layout and design of the chemical or other plant, but in its location, layout, design, finance, operation and management. These factors properly engineered make scientific management.

This subject is big enough to fill volumes, so I may only describe briefly and in outline the development of a plant, and while it all seems obvious, I know, from the experience of one who has been laying out plants for 20 years, that a scientific analysis of these factors is, at least until very recent years, usually neglected.

Scientific Plant Development Formerly Neglected

Until within recent years the manufacturer regarded his buildings merely as structures housing the equipment and consisting merely of four walls, roof and floors. Neglect of consideration of the type of building best suited to the occupancy or manufacturing processes was followed by neglect of the arrangement of the buildings comprising the plant or their interrelationship.

The result has been in most plants a hodge-podge of buildings built one at a time without reference to co-ordination of manufacturing operations, without thought for future growth either as a whole or for single units or departments, and without thought, in very many instances, of the physical comfort and welfare of employees.

Development of a Plant

This analysis may be the work of a plant engineering staff or of a consulting engineer. Few corporations can command the exclusive services of engineers of broad experience and for this reason has developed the profession of industrial engineering—i.e., the engineer of industry.

The development of an industrial plant project can best be outlined by the steps to be taken. These steps may be listed in their order as:

1. Location.
2. Layout.
3. Design.
4. Construction.
5. Equipment.

Location

Location should be considered with reference to:

(*a*) Supply of raw materials.
(*b*) Market for finished products.
(*c*) Labor supply.
(*d*) Transportation for raw materials from source to supply.
(*e*) Transportation for finished products to market.

Each of these factors requires careful and scientific analysis.

Raw Materials

Raw materials must be of the proper quantity and quality. The supply must be constant, stable and inexhaustible. Substitutes for materials ordinarily used offer large opportunities for increased production and profits. Industrial chemistry enters into this question very largely. New materials developed through chemical research frequently develop entirely new industries. Many existing industries and most new

industries owe their being to the chemical research of the industrial engineer. Freight rates and speed of rail or water transportation affect the raw material supply.

Market

The market for finished products takes into account the amount of consumption within the economical limits of distribution. This applies to the corner cigar store as well as to the tractor plant which ships to points within a radius of a thousand miles.

Labor Supply

The number of people available in a given section, their nationality, training, experience, education, availability, all affect the labor supply. The steel mill, the foundry or the factory employing men, women or children must be accessible to the type of people whom it desires to employ. Many factories are failures because they cannot obtain the services of the class of employees they require, in competition with other plants in locations more accessible or otherwise attractive to the employee.

Transportation

Transportation as a factor of cost of the product must be considered with reference to both raw material and finished product. Not only are there limits above which freight rates cannot go, but the rail or water service must be continuous, direct and of minimum time. If intermittent, surplus supply must be contracted for and provision made for handling and storage. The ore from the Lake Superior mines and coal to points on the Great Lakes can be transported during only 8 months of the year. Mountains of ore and of coal must then be stored to provide for the consumption of the winter months. Labor can be moved and markets created, but the necessity for and cost of transportation remain fixed, and so are often determining factors in locating a plant. Assuming that the city in which the plant is to be located has been determined upon, it is necessary to analyze the needs of the location within the city:

(*a*) Transportation of raw materials and finished product by water, rail or truck.
(*b*) Labor supply accessible to plant.
(*c*) Transportation of labor within reasonable limits of time and cost.
(*d*) Special requirements such as water, power, coal, sewage disposal and waste disposal.
(*e*) Adequate and suitable shape and size of land for present and future building operations.

It is granted that these points seem obvious, but the fact remains that however important may be their consideration, the failure carefully to consider, investigate and study has resulted in very many poorly situated plants.

Layout

The second part of the engineer's problem is the making of a layout which embraces the following essentials:

(*a*) Delivery of raw materials to plant.
(*b*) Storage of raw materials.
(*c*) Introduction of raw materials into manufacturing process.
(*d*) "Straight line" process of manufacturing.
(*e*) Storage goods in process.
(*f*) Storage finished product.
(*g*) Expansion of each or every department for future needs.
(*h*) Handling of materials through and between departments.
(*i*) Machine layouts.
(*j*) Special equipment—ovens, furnaces, vats.
(*k*) Employees' facilities for physical and mental well being.

A detailed analysis of all these points is a matter of indefinite length and in no two instances are the conditions identical; therefore no hard and fast rules can be set.

A few fundamentals may be mentioned, however, which are universally applicable and which should always be considered.

Elimination of Man Power

On the assumption that somewhere between ten and fifteen thousand dollars can be spent to eliminate permanently the employment of one man, careful consideration should be given to the problems of delivery, storage and handling of raw materials. The use of bridge cranes, gantry cranes, jib cranes with monorails, chutes, bins, vats, tanks, buckets and elevators should all be analyzed and the merits of each one carefully considered with a view to eliminating man power and substituting therefor mechanical handling equipment.

Routing of Materials

The second fundamental is the routing of goods through the plant—in other words, the employment of a straight line flow of materials, or expressed in still another way, the placing of all manufacturing processes in their logical sequence in the plant. It is frequently possible to reduce a travel of goods from raw to finished stages from 1,000 ft. to 200 or 300 ft. of travel. This means reduction in the floor space and cost of handling. Frequently entire departments can be relocated to secure advantageous flow of material and effect reduced production costs.

Handling of Materials

The third fundamental is the handling of parts, either in process or finished. Economy is effected by careful distribution, and an accurate knowledge of quantities required for each operation leads to enormous savings in the amount of stock carried. A lack of materials in necessary quantities and at the right place makes a delay in filling orders and a consequent loss of time that could be entirely eliminated by a careful study of the materials required and the location at which they are needed.

Automatic Equipment

The fourth fundamental is the use of modern equipment. This means equipment by the operation of which savings in man power are effected. A machine which will save the permanent labor of one man can well be installed at a cost of ten or fifteen thousand dollars and there are new plants where large economies could be effected by modernizing the equipment. Instances can be cited by the score where production has been doubled by the installation of labor-saving equipment and machinery. The result is larger wages to the employees, the larger wages being cheerfully paid to increase the production without the making of other capital investment, such as larger floor space, to obtain the same reduction.

The fifth fundamental is the introduction of new processes or equipment developed for special purposes.

This is so obviously a specialized problem that generalities are valueless.

Considerations of Welfare

The sixth fundamental is the consideration of the welfare of all employees. This involves the question of better surroundings with abundant light and air, adequate rest rooms, lunch rooms, recreation rooms, retiring rooms and other rooms for mental as well as physical well being and development.

Volumes have been written, and are being written, on each one of these phases of industrial development. The solution of these problems makes for the welfare of every man and woman connected in any way with industrial operation, and it remains for those in responsible charge of industrial operations to make the most of this opportunity for the good of themselves, their industries and their country.

Design

The physical plant which comprises the buildings can be determined after the layout is made. First must be determined the necessary clearances, both vertical and horizontal. This means heights necessary for manufacturing purposes, including vats, tanks and piping. It also means the shape of the cross-section of the building which is necessary to give these facilities and at the same time to provide light and ventilation. This means warmth in winter and coolness in summer. This is not always easily obtainable and it is only through experience and careful analysis of governing conditions that a satisfactory solution may be obtained. For instance, a foundry requires better ventilation than a machine shop, and in turn a machine shop with its equipment requires better light and ventilation than a plant in which there are comparatively few operatives. A chemical plant requires, as a rule, a maximum of ventilation to comply with increasingly rigid state laws.

Light and Ventilation

It is obvious that both light and ventilation may be classed as natural and artificial. Natural ventilation depends entirely upon the contour of the building, as does natural light. There are many instances where artificial ventilation is beneficial to the manufacturing process, as well as to the operatives. Proper artificial light is responsible, as tests have conclusively proved, for 15 to 25 per cent in increased production. Good lighting therefore means a good investment. Proper ventilation means increased production.

Heating of Buildings

Heating is akin to ventilation and a uniform proper temperature must be maintained in order to obtain maximum production. The question of heating involves that of power, and there is a nice balance to be determined between the costs of heating with purchase power versus heating plus manufacturing power. The engineer must be competent to make a careful analysis of heat and power costs. In this connection, too, are involved the use of steam, air and electric current for power and heating.

Sanitary installations must embody the up-to-date features which mark the modern building. Consideration is due this subject from the standpoint of health and happiness of the employees.

Buildings may be built of timber, steel, concrete or a combination of these materials. The market price of the materials, the rates of insurance, the anticipated life of the buildings and charges for maintenance and depreciation are all items to be considered and each individual case must be settled on its merits. The day of flimsy firetraps for the occupancy of human beings are rapidly passing and the science of fire protection and prevention not only means adequate protection for fire-fighting facilities, including standpipe, sprinklers, hose connections, etc., but also the consideration of fire-proof partitions, inclosed stairways and proper spacing of buildings with ample entrances and exits.

The question of design cannot be passed by without a word regarding the desirability of worthy architectural treatment. It costs no more to design an attractive building than a building which is ugly, and the basis for an attractive plant is an attractive building. The modern industrial building is frequently as attractive as a modern hotel or apartment house, and deservedly so. The morale of an entire organization is lifted and benefited by attractive surroundings. The worker acquires a pride in the plant where he works which is attended by a definite improvement in production and loyalty.

A further advantage to be derived from the attractive plant, and one to which far too little notice has been given, is the advertising value inherent in it. A photographic cut of an ugly, ramshackle or unkempt factory would do anything but establish the prospective buyer's confidence in the product. On the other hand, a good product has a natural mental association with a good-looking plant. Also, travelers passing a plant of good appearance retain the picture and the company's name imprinted on their memory, while the plant of undistinguished appearance soon fades from the mind.

Construction

The proper construction of a plant means the execution economically and in a minimum amount of time of the plans and specifications of the designing engineer. The method of execution of construction varies, obviously, with each job and is dependent on factors of materials, labor costs and supply. Nothing is gained by the employment of irresponsible contractors, or in an attempt to curtail costs below a reasonable figure which must include a legitimate profit to all parties concerned.

Equipment

Equipment installation has been mentioned in connection with plant layout, and the only comment necessary is to emphasize the point that modern labor-saving equipment frequently means the difference between profit and loss. No manufacturer can afford to keep in his plant a dollar's worth of equipment which does not show a profit, and he cannot afford not to purchase new equipment when the further investment shows a saving of labor or material costs which will result in profits on the capital invested. This is the essential of equipment.

The elements of a successful business are—plant, equipment and personnel. It is only when these three essential functions are co-ordinating properly that we have successful operation—i.e., low cost production—and all of the elements which have been discussed in various paragraphs above are worthy of serious consideration to the attainment of this end.

This is the science of man and material—mental and physical. The co-ordination of these spells success in plant operation.

Chicago, Ill.

Increased Efficiency Through Industrial Training

The Training of Foremen in Production Methods Offers the Best Opportunity to Enlist the Key Men of Industry in Teamwork, Loyalty, Watching Costs, Cutting Wastes and Increasing Quality and Quantity of Product

By B. M. Nussbaum
Vice-President, Business Training Corporation

TWO years ago a large sugar refinery on the west coast became interested in industrial training. It was frankly looking for some plan that would raise the level of efficiency of its force and enable it to introduce economies that the descending business depression made absolutely necessary. The management finally decided that foreman training promised the largest measure of results. A program of 3 months' intensive drill in production methods was accordingly adopted, and more than 200 of the foremen and leading men were enrolled.

At the time this course was being given the refinery was running full capacity and full force, but a few months later the demand fell off sharply, production had to be reduced to 1,000 tons melt per day, which is about half the normal capacity, and of course this meant that a considerable number of men had to be laid off. There came a time last fall, however, when a sudden spurt in market demand called for a quick temporary increase in production. For 2 weeks it was necessary to raise the production to 1,400 tons per day.

It may seem a remarkable statement, but the simple fact is that this sudden 40 per cent increase in production was accomplished without making an increase in the force. The foremen displayed a brand of resourceful teamwork in meeting the emergency which exceeded the superintendent's highest hopes, and the production was got out on time and up to the highest standards of quality. The superintendent attributes the showing made in large measure to the industrial training program which had taught the foremen how to pull together, and the principles of which they were quick to apply under the severe strain of an emergency.

Increased Production Following Training

Production in the rolling mill of the National Stamping & Enameling Co. at Granite City, Ill., increased 34 per cent after the company had installed a system of foreman training. This statement was publicly made by an official of the company at a convention, and he attributed the increased production largely to the greater teamwork and individual ability developed among the foremen by their training.

Swift & Co. have applied foremanship training on a truly comprehensive scale, nearly 5,000 of their foremen and other production executives in twenty-eight of their plants in the United States and Canada having followed through to completion a course in production methods. This company's experience records many examples of efficiencies accomplished through the effects of the training. An outstanding example is given in the production record of an Eastern plant, where one department manager by applying principles drawn from his training increased output from 400 units per man to 700.

In a paper mill the production of one department was increased 42 per cent through an improvement made by a foreman after he had been a short time in a training course. The foreman frankly admitted that the improvement had been suggested by what he read in one of the textbooks of his course.

Many more examples might be cited to illustrate the effect of training on ability. In many cases the concrete result is an improvement in the quality of the production. In others, as in those cited above, definite increases in output are attained. In many more it is impossible to trace concrete results that may be set down in exact figures. Here the influence of the training shows up in better human relations within the plant, more capable handling of the men by the foremen, a stronger loyalty to the plant organization as a result of the clearer understanding of what the organization is, better teamwork all around as a result of the keener sense of one's place in industry as well as better understanding of the production principles and methods taught. Very often these intangible fruits of training, which do not lend themselves to recording in the cost sheet or the profit-and-loss statement, really affect costs and profit and loss in a way that is far reaching and undeniable, even if indefinite.

What Is Industrial Training?

Perhaps it will be worth while to consider the type of education that has produced such results. Industrial training is a broad term, and may mean different things to different people. The education embraced under that heading may range all the way from highly technical instruction in technological subjects to elementary education in reading and writing such as is given by some plants in night schools for the benefit of foreign employees. But strictly speaking, we rule out classes in general subjects as belonging to common school education, and all the higher technological training as being really professional or engineering education, and what is left we classify as industrial education in these two classes:

1. Vocational and continuation courses in the plant or under its auspices. Such courses are intended mainly as preparatory, to break in new employees, fit beginners for jobs, and prepare present employees for promotion or assignment to other work. Examples of how this training is organized may be seen in apprentice schools, vestibule schools, shop schools, continuation schools, and the like.

2. Training in the job and on the job as an integral part of the operation of the plant. The object here is not primarily to break in beginners or to fit employees for promotion, but rather to give the individuals in the organization an understanding of their work and of its interrelations in the plant and in industry, to inform

them of the basic principles and approved methods of production, to motivate them for greater efficiency, and to stimulate them in accomplishing it. Of course not every training system accomplishes all of these results; some may narrow their purpose more than others. Examples of this training are given in the production classes and study groups organized in a number of industrial establishments within the last 5 years, and more especially the courses in foremanship training.

Of all this educational work, foreman training is to my mind the most important and the most resultful. All industrial training has value. There can be no question that if a suitable training program is intelligently applied to any group within a plant, the results will be beneficial to the individuals and to the plant as a whole. But I know of nothing that will work such results as a system of foreman training, carefully adapted to the requirements of a given group of foremen and systematically followed by them. The foreman is the key man in industry. It is difficult for the men of a department to accomplish improvements without the leadership of their foremen. It is practically impossible for them to make much headway without his sympathy and encouragement. All of the examples of increased production cited at the beginning of this article are results of foreman training.

Why the Foreman Is Important

"Most of the improvements, policies and ideas of a company stop at its foreman," said H. L. Willson, vice-president and general manager of the Columbia Graphophone Manufacturing Co. "They are not transmitted to the rank and file of employees. The most elaborate safety campaign may be entirely negatived by a careless and indifferent foreman. The most convincing health campaign may be rendered futile by the foreman with a sneer. The most patient study of operations and most scientific reorganization of working methods may be entirely wasted by the foreman who tells his men to 'fergit it' when the reorganizers are on the other side of the door. The smoothest and most successful of production routines may be disorganized or smashed by the whim of a foreman who is ignorant of the working of the whole plant. The friendliest kind of relations between executives and employees, the most careful of employment methods, may be wiped out and a high labor turnover piled up by a tyrant foreman. The most enlightened and earnest labor policy may be distorted into an object of bitterness and resentment by a few words from a cynical foreman with a grouch. In every phase, at every point, the work of the executives may be made or marred by the foreman."

And the opposite of this picture is also true. If the management has a new working plan that it wishes to put across with the force, if it has a new schedule to be installed or a revision of rates to be announced, it can have no better ambassador to the men than a foreman who is clearly informed of the management's policy and in intelligent sympathy with its plans and purposes. The necessary salesman of new ideas within the plant is the foreman.

The head of a large textile company estimated recently that his company saved more than $100,000 in 1921 through improvements resulting from employee suggestions. These suggestions, he says, were in large measure the result of good foremanship. Most of the suggestions really came from the mill and department heads and their assistants, and the remainder came from the rank and file who through better foremanship were stimulated to better teamwork and more intelligent thinking about production problems.

Production efficiency comes from the maximum utilization of men, machinery, methods, materials and money. The foreman does not have committed to him much direct spending of the firm's money, but he is directly responsible for the utilization of the four other elements enumerated. And by his handling of these elements he influences the spending of money.

When training is applied to the foreman, therefore it is applied at the most strategic place in the entire plant organization. The foreman in the average American plant is the management to the men under him. They judge the management by their foreman, and their respect for and loyalty to the plant is in direct ratio to their attitude toward their foreman. Train a foreman, and you not only put a key man to thinking intelligently in terms of production efficiency, but you can be certain that the men under him will also receive some of the foreman's training. He will pass it on. As the personnel manager of a Western plant put it, in describing some of the results of a foreman course in his organization: "The foremen become instructors and inspirers of their men in the training. Each foreman becomes a center for its propagation. Thus through the foremen themselves, the ideas reach the rank and file."

Four Kinds of Training

After a plant management has decided to provide training for its foremen, the problem is by no means settled. What kind of training? The choice is a wide one. There are highly technical courses, popular lecture courses, round-table conference systems, extension courses provided by universities, standarized courses, individual plant courses conducted by the management, courses conducted by outside training organizations. While there is this apparent great variety, it is possible to classify the various systems into four groups:

1. *Company Training Systems.* Several industrial companies have organized and conduct training for their foremen. Examples are the General Electric, Goodyear Tire & Rubber, American Steel & Wire, and International Harvester companies. For the most part, these courses are fairly technical, and, while comprehensive, stress the individual processes and problems of the particular industry.

2. *University Efforts at Foreman Training.* Some of the universities that are located in industrial cities have taken up this problem. An example is the work of the University of Pennsylvania, under Prof. Joseph H. Willits. Meetings were held in the auditorium of one of the city high schools attended by about 500 foremen selected from different industries in and around Philadelphia. At each meeting there was a lecture on some industrial topic. The lecture lasted from 35 to 45 minutes, after which the meeting broke up into smaller groups, each group adjourning to a room in the building for discussion and questions. A mimeographed digest of the lecture was distributed among the foremen a week in advance, thus giving them an opportunity to prepare themselves somewhat on the subject to be discussed.

3. *The Informal Conference System.* This is the plan for foreman training proposed by the Federal Board for Vocational Education in November, 1919, and it has been applied in various ways in a number of industrial plants. In brief, this is a system of periodical meetings of the foremen in small groups under a leader for informal discussion of plant problems by the foremen themselves.

4. *The Standardized Course.* Here the training is based on a standardized course which makes use of specially prepared textbooks and requires problem work. It is usually conducted by some outside training organization. In some of these courses lectures are used to reinforce the textbooks, and also to tie the training directly to the work of the individual plant, as well as to bring an element of inspirational leadership into the course that mere textbook study or classroom routine cannot give. An important feature of this system also is the group conference for questions and discussion.

Some Differences in the Training

Each of these four methods of training has its advantages and its disadvantages, and before adopting any system a careful management will give close attention to the differences inherent in these systems and to the special requirements of his own foreman-training problem.

There is one conspicuous advantage of the company course. It is planned especially for its own organization, built with one specific industry and group of foremen in mind. Too often this advantage is lost by overelaboration or too much specialization. The creation of such a course is, moreover, expensive and venturesome. Such a project should not be entered on without the most careful planning and balanced execution on the part of those intrusted with the training. Foreman training does not mean highly specialized instruction in the technique of the industry. In the temptation to make it highly technical lies the great danger in planning any foremanship course—and very often it is just this overemphasis that handicaps the success of a company course.

Universities have the advantage of organization, prestige and, to a rapidly increasing degree, experience in the field of business and industrial education. For picked foremen of an exceptionally high type of mind, lecture courses by specialists on the various subjects of industrial management may be extremely helpful, informing and stimulating. But for the average foreman they are no substitute for courses conducted in the plant or near to it, and therefore under less formidable auspices than the name "university" suggests to the average man of mechanic type. Moreover, the method of instruction, while suited to the exceptional foreman, would soon lose the interest of the average. Few managers regard this plan as a satisfactory substitute for organized training in the plant.

The Federal Board plan is the very opposite of the highly specialized comprehensive course, and it has the advantage of not being complicated or cumbersome in installation and operation. Nor is it expensive. It has the further advantage of being easily focused on plant processes and problems. But its very informality of study material and method involves a serious weakness in that only the exceptional foreman can be brought to make the most of a conference. In a typical group of foremen, meeting together with their feet under the table for free and easy discussion of plant problems, one or two natural-born "talkers" will monopolize the meeting. The rest of the foremen will sit around, silent for the most part, occasionally putting in a word or a laugh, maybe, to show some apparent interest in the meeting; but in general they will get little out of it. If any real ideas are developed at such a conference, too often they are just so much talk to a majority of the men and fail to sink in. The typical foreman is a slow thinker; he learns for the most part by the slow process of experience. That is why any process of training that requires the quick reaction of mind to mind in the hit-or-miss discussion of a round-table conference is less successful with foremen than one which organizes the study material onto a form easy to read and understand, and then adds to this simplified presentation some incentive to follow the study and apply the principles and methods taught.

This brings us to the standardized course. The standardized course deals with the problems of foremanship in terms of basic principles, and seeks to lay a broad foundation of fundamental facts of industry and of human relations within industry that will help the foreman to function better no matter what size of type of plant may be the scene of his foremanship. It is my belief, based on several years' experience training foremen in several hundred industrial plants of the United States and Canada, that the standardized course offers the manufacturer or industrial executive the most competent and practicable means available today for developing foremanship ability. The system has been used in practically every type of industry, it is elastic and easily adapted to various sizes and types of plants, and lays a foundation of basic knowledge about production work upon which more advanced educational efforts can be successfully built. Perhaps the only disadvantage ever voiced against this system was by those who wished a course built especially for their plant and who objected that the standardized course was too general. By reinforcing the study work with lectures given by men who are capable teachers, this objection has been overcome, and in hundreds of plants the standardized course has been focused upon the individual problems of the plant, with results truly remarkable.

Four Training Essentials

In the organization and operation of a successful standardized course, four elements have, in my experience, been found essential to the best results: (1) Text material containing the basic teaching of the course written specially from the foreman's angle and in a style easily grasped by the average foreman type of mind. (2) Lectures in amplification of the text material and applying the principles and methods taught to the processes and problems of the individual plant; an essential feature here is the personality of the lecturers—they must be men who not only know industry and production methods, but also have teaching ability. (3) Problem work calling for definite home study on the part of the foremen-students and giving them experience in applying the production principles taught. (4) Group conferences for discussion of the principles and methods taught in the course and for clearing up questions that arise.

Text, lectures, problem work and group conferences must not only be properly balanced, but the foundation of success in such a training system lies in the proper choice and presentation of the subject matter. As I have said before in this article, foreman training does not call for highly specialized instruction in the technique of the foreman's job or department. The average foreman is pretty well informed in his own line of work. He knows his machine, his process, his department better than any one else—at least, he thinks so—and is apt to resent anyone's coming in to teach him his own job. But when you come in to tell him how other plants are managing, what foremen are doing to meet their problems of organization, discipline, spoilage and the like in other industries, you immediately get a reaction. The foreman is interested in these concrete examples; and unconsciously he is influenced to apply these new ideas to his own production problems.

One of the executives of Swift & Co., discussing this question of what material should go into a foreman course, said: "Let him find out how other plants are managing men, selecting, disciplining and training them; how they are keeping track of materials, learning costs and eliminating wastes; how they are organizing so that the functions of each man fit into those of his associates, thus making for better teamwork. Let him find out these things, and he will rise above the walls of the rut he has dug and see possibilities in his job that he never dreamed of. He will learn that there are ways of doing his daily tasks better than he has learned to do them; that the responsbilities of his position are really greater than he imagined. And his ambition, pride, alertness will be aroused; he will produce more for himself, and in so doing produce more for the company."

Proof That Foremen Will Study

A short intensive course, organized and conducted as suggested, sustains the interest of the foremen students to a remarkable degree. One of the stock objections to foremen training has been that foremen won't study. They may attend lectures, they may sit in at conferences, say these critics, but very few of them will really apply themselves and study. I have records of foreman training in more than 300 plants, in groups ranging from several hundred down to less than a dozen; in only 6 per cent of the plants do the results show a completion record of less than 50 per cent; in the majority the percentage is far above that figure. From these records I cite the following examples from industries that may be of special interest to readers of *Chemical & Metallurgical Engineering:*

	No. of Men Who Enrolled	No. of Men Who Finished	Percentage of Men Who Finished
Carpenter Steel Co.	69	63	91
Corning Glass Co.	244	232	95
Detroit Steel Castings Co.	28	25	90
Federal Rubber Co.	93	81	87
Gutta Percha Rubber Co.	128	116	90
Portsmouth Cotton Oil Co.	24	23	98
Simplex Wire & Cable Co.	35	34	97

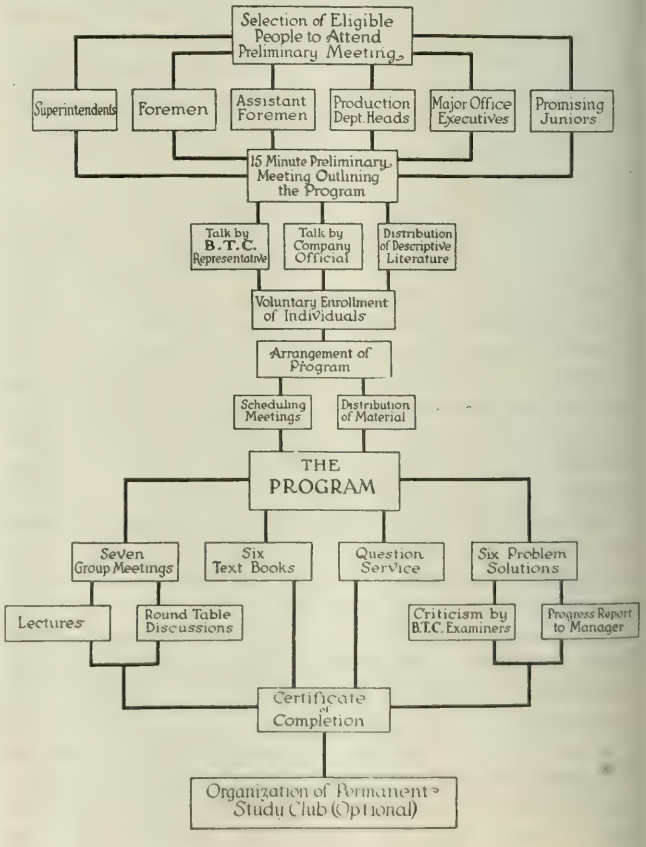
The proof that they benefit by the result of their study is found in the innumerable instances of improved work, better direction of a department, reduced friction in the handling of men, increased quality and quantity of output and other evidence that might be cited from the experience of plants where foreman training has been conducted. A few examples have been given at the beginning of this article, and many more are on record. Many companies have used the training as a foundation on which to build more specialized courses. Such courses have been found practical after the foremen have received the bedrock of basic production principles taught in the course and have been accustomed to study methods. In a number of instances, in fact, the men themselves have demanded some sort of continuation work; and this has usually taken the form of "Production Clubs" organized and manned by the foremen for the discussion of production problems, to keep abreast of production technique in the industry and to furnish a sort of foreman's council or cabinet for handling the questions that come up.

Thus a course in foreman training, if it is rightly conceived and conducted, becomes more than a temporary focusing of attention on production. It becomes the starting point and the foundation stone for continued work and for permanent improvement in the foremanship of the plant.

New York, N. Y.

Procedure in Foreman Training

Next in importance to the actual training of foremen is the method of procedure by which they are interested in and familiarized with the course of instruction. Manufacturers and executives who may have convinced themselves that foreman training is a good thing may still be in doubt as to the correct answer to the big question, "How shall the training be organized and conducted?" Those who have had experience in this sort of work have developed certain fundamental facts that apparently are requisite for success. The Business Training Corporation, for example, has charted its idea of the best procedure in the accompanying diagram which we reproduce from that organization's recent publication entitled "Twenty Thousand Better Foremen." The chart quickly visualizes the essential steps in organizing classes in foreman training.



The Design of Chemical Plants

Chemical Plants Generally Not Good Examples of Studied Design—Opportunity Is Good for Introducing Improvements From Analogous Industries—The Controlling Factors in Plant Design Should Be Efficiency in Material Handling and Allowance for Future Expansion

By A. E. Marshall
Consulting Chemical Engineer

When a survey is made of operating costs in a chemical manufacturing plant, labor often bulks high, and while in high-priced commodities this may not cause inquiry or create a desire for investigation, yet in a low-priced article a high labor cost may mean not only a loss of profit but even a loss of business if demand is small and competition keen. Elsewhere in this issue various phases of cost and suggestions for lowering cost by increasing efficiency are discussed. This article is concerned with one important phase of operating cost—the handling of materials through the plant and the influence of plant design on the cost of pre-process and process labor.

Chemical Plants Not Examples of Good Design

Chemical plants as a whole are not striking examples of studied design arranged to obviate the use of labor in everything except its minimum essential form. The reasons for this vary—some plants have grown up around a small semi-commercial experiment, expanding as demand for the product arose; others, operating by rule of thumb, are equally rule of thumb on the engineering and design side. Still another reason lies in the fact that many plants operating today have not been changed in any essential detail for years, possibly since their original construction.

Most of the plants built during the war period were designed not for low-cost production, but by force of prevailing circumstances were arranged for the use of equipment which was available for delivery within a reasonable period.

There is, in the writer's opinion, room for considerable revision of engineering practice in chemical plants and for close study of the results obtained in other industries where the problems of manufacture are analogous to those presented in the chemical industry.

Material Handling a Controlling Factor

The need for efficiency in handling materials through the stages of chemical processes is more pronounced today than at any previous time in the history of chemical manufacture. Labor has not gone back to pre-war rates, and studies of the cost of living and correlated subjects indicate rather clearly that a return to pre-war figures cannot be counted on in any serious consideration of costs of operation.

The consumers of chemical products demand today standard grades at low prices, and the manufacturer who has consistently cut out surplus hand labor by the substitution of cheaper mechanical labor, who has routed movements of material, thereby shortening travel, is the manufacturer operating close to capacity and employing high total labor, but on a basis of low labor-hours per ton of product.

Conditions Governing Handling Equipment

In any consideration of mechanical handling there are certain fundamental conditions which must be met by the mechanical device. Interest on the capital expenditure involved, depreciation, repairs and labor cost for supervision must be less than the cost of the same operation carried out entirely by man power. This would seem to be a condition which would always receive first consideration, but examples could be cited from many plants to prove that a complete study of the cost of operating some mechanical device had not been made prior to its installation. Another essential is that the device must be capable of withstanding the unusual conditions of chemical plant service. A loading machine which handles sand will not necessarily have the same life when used on acid phosphate. It is not unusual to find that excessive corrosion, which is so often a feature of chemical plant work, makes it necessary before success is obtained to rebuild, with different materials, a machine which has given excellent results in some other industry.

Another important consideration is continuity of operation. Mechanical failure must be taken into account, and it often happens that too much trust in mechanisms, without provision of a safety bypass in the shape of a transfer of material by hand power, leads to a prolonged shutdown and to lessened output. In chemical manufacture, continuity of operation is generally much more important than in other industries. The volume and cost of output of a chemical process usually depend on the simultaneous carrying on of a number of stages of manufacture, and a shutdown of one stage adversely affects the other stages. This calls for close study not only of the desirability of being able to arrange temporary bypasses but also of the possibilities of failure in mechanical devices. Mechanisms adopted without change from other industries may give trouble, because the parts, while sufficiently strong to take care of materials of fairly uniform density, consistency, etc., are not strong enough to stand up under the variations of load and quality of load which result from some temporary disarrangement of a chemical process.

The question of plant design is so closely linked with the use of mechanical handling devices that beyond pointing out, as has already been done, some essential features of satisfactory mechanical equipment, the two subjects will be treated together.

Factors to Consider in Design of a New Plant

In considering the design of a new plant, the chemical engineer has several important factors to take into account. One which has received least attention in the past and one which has caused later on in the life of chemical plants either unnecessary cost of product or prevented possible reductions is the lack of provision for future expansion.

A successful plant necessarily meets with a demand for increased output, but unless the original design took care of the future need, the expansion either takes the form of a replica of the primary layout or the additions are crowded in wherever a vacant space is found.

In either case, lower costs are not likely to follow increased output.

If the design properly takes care of expansion, then certain parts of the plant mechanism can be worked at full load instead of being duplicated, and the same labor will perform more work. There should be greater economy in producing 50,000 tons of product in one plant than in turning out the same tonnage from two 25,000-ton plants or from a 25,000-ton plant which has been painfully stretched to give 50,000 tons.

Indefinite expansion cannot be provided for in design except by arranging for duplication, but doubling or even trebling the output can usually be taken care of by adding equipment in locations which were fixed by the layout of the original plant.

Other essential considerations are the receiving and storing of raw materials, the storage of finished products and the flow of materials from the raw to the finished product stage.

The Flow Sheet in Plant Design

In the metallurgical industries, a flow sheet is the starting point for consideration of any process or new plant. In the chemical industry it often happens that a flow sheet, when one is made, is worked up after the plant has been built and operations have been begun.

A large-scale flow sheet, showing daily tonnages moved at all points, and with maximum storage capacities for raw and finished products, should be the first step in designing a chemical plant.

Study of the flow sheet will bring out the salient features of the operation, and will suggest various arrangements of equipment and buildings which can be further studied by making experimental layouts in outline.

The flow sheet with its indicated tonnages and the outline layouts will show the points where handling of materials take place, and a decision can be reached as to whether a mechanical device or hand labor is desirable.

Possibilities of Equipment Developed for Other Industries

The chemical industry has been rather slow in the adoption of mechanical handling equipment, and even if there is no known parallel use of machinery for a certain purpose in chemical plants, it generally pays to make a survey of the use of equipment in other industries.

As an example, the use of bridge cranes may be mentioned.

Up to a few years ago bridge cranes were not employed in chemical plants, although in other industries they were enabling large savings to be made in the handling of materials.

Bridge Cranes for Handling

Today many chemical plants, particularly fertilizer factories, rely on bridge cranes for the movement of raw, intermediate and finished products, and by refinements in the design of the plants all the stages of production have been placed within range of the crane. A bridge crane represents a high initial investment, but it shows a good return when given sufficient tonnage to handle. As an example, a single bridge crane in a fertilizer factory can be utilized for all of the tonnage movements including:

Raw phosphate rock to storage.
Rock from storage to mills.
Acid phosphate from dens to storage.
Acid phosphate from storage to bulk shipping poin
or mixing department.

If the plant includes a mixing department the sam crane can handle potash, ammoniates, tankage, etc., t and from the storage bins and mixing and screenin machines.

Proper Arrangement of Departments

Careful planning of the operations cycle is neces sary when a bridge crane is called on to serve variou departments, otherwise the crane will waste time i travel with an empty bucket. Also the placing of de partments demands study so that in a fertilizer plan raw phosphate rock does not have to be moved ove the storage piles of acid phosphate. A leaking gral bucket, loaded with phosphate rock, which had to trave over stored acid phosphate might mean a serious los through a portion of the rock finding its way into th official sample. Here again a study of a flow sheet in plan, will obviate the need for changes after construc tion is completed.

Where a Monorail Should Be Used

While a bridge crane represents the maximum facility of tonnage movement, it frequently happens that the total weights to be handled do not justify either the installation or operating cost. In such cases it is often possible to incorporate a monorail crane system in the design, and to move materials by monorail grab cranes or tubs at much lower cost than a combination of conveyors, elevators and hand labor. The disadvantage of a monorail is its fixed position, which differentiates it from the free traverse of the bridge crane. A proper arrangement of plant units will, however, in most cases give the monorail system an opportunity to perform all the tonnage movements. It should be remembered that a monorail system is not really limited to the use of grab buckets. Movements of materials originating off the direct line of travel can be taken care of by a hook crane which picks up tubs transferred under the monorail by means of hand cars on a narrow gage track.

The inclusion of a weighbridge in the monorail track is often desirable, as it permits the weighing of furnace charges, etc., without the expense of double handling to and from a platform scale.

In the case of handling problems where there are two active lines of travel at right angles, it often proves advantageous to utilize two monorails at different levels. Transfers of material can be made by hook cranes and tubs or a transfer pit can be built for the use of grab cranes at the junction point.

Other Types of Handling Installation

Elevators and belt conveyors are familiar devices in chemical plant practice, and call for no special mention. Pan conveyors capable of handling hot or abrasive materials are now coming into use, and have already solved some problems which previously had been considered as capable of solution by hand labor only.

Each plant has of course some special handling problem which lies outside the general treatment of this article, so a tabulation is given of some of the labor-saving devices which have found application in such work in recent years.

Pneumatic conveyors of the air pressure or vacuum types.
Vacuum unloaders for ships and cars.
Storage battery trucks.
Skip hoists.
Mechanical car unloaders.
Narrow-gage electric and gasoline trolley systems.
Portable conveyors.
Box-car loaders for bulk products.

Providing for Raw Material Storage

One phase of plant design work which scarcely ever eceives attention until the need presents itself is the rovision of outdoor storage for raw materials which re not affected by the weather. Convenient covered r uncovered storage for such materials is of course an ssential provision of the original design. At some ime in the plant history raw materials accumulate in xcess of the storage capacity, and as there is no op- ortunity for arranging adequate new storage, the mate- ials are piled in the factory yard either by a locomotive rane or a portable conveyor. The provision of tem- orary trackage and the difficulty of making a clean-up re serious items in the cost of temporary outdoor torage.

If space for outdoor storage is provided alongside ne of the permanent standard-gage tracks, a low-cost system of handling can be developed by the aid of a locomotive crane equipped with a grab bucket and mounted on caterpillar tracks. Such a crane has complete freedom of movement without the need for laying tracks and can recover a storage pile to the limit of grab bucket recovery without the use of a shovel gang. The locomotive crane with caterpillar tracks is also a valuable machine in other parts of the plant and has even been utilized in the case of a breakdown to replace an elevator.

The Plant Designer Must Investigate Other Industries

In conclusion, a statement is advanced that the chemical industry of today does not generally utilize to the best advantage mechanical devices for saving labor. The trend of prices makes it essential that the chemical engineer and the manufacturer study closely results which are being obtained in other industries with labor-saving devices. Some of these devices may need to be changed either in material or in the strength of parts before they are entirely suited to chemical plant usage —but the chemical engineer should be the one to investigate the possibilities, and to suggest to the equipment manufacturer the changes which are necessary to fit his machine to the needs of the chemical plant.

Baltimore, Md.

Increasing Heating Furnace Efficiency Through the Use of Insulation

Increased operating costs and keen competition have irected attention to many losses in the use of heat vhich were formerly disregarded. Prominent among hese is the loss of heat through heat-treating furnace valls.

Design of Heating Furnaces

Furnace design and operation is probably the most nexact branch of engineering science. This is because esults can be obtained that are satisfactory even if the nethods are wasteful; and because it is extremely diffi- ult to keep an accurate record of just what goes on nside the furnace walls.

Also, the prime consideration in the past has been to lesign the furnace to get the maximum production of ngh-class material; and methods of heating have only ecently come to get the consideration which they must ecessarily have in a period of high fuel costs.

At the present time, designers of heat-treating fur- aces are fully awake to the necessity of constructing heir furnaces so as to attain the greatest possible effi- iency of operation. As a basis for this design it is ecessary to find out where the heat goes and in what roportion.

Distribution of Heat

The heat generated in a heat-treating furnace goes in part to do the heating required and is in part lost through the walls and doors and up the stack. The heat required for the work and that lost up the stack are, in modern, well-designed furnaces, already kept at a minimum. It is to the reduction of losses through the walls and doors that we must look if we are to save heat through further improvements in design.

In the design and construction of heat-treating furnaces the conductivity of fireclay is of extreme importance. In oven furnaces, where a large volume of heat is required, particular attention must be paid to the conductivity of the firebrick employed, so that the thickness of wall may be determined to give the most economical working.

In the case of small furnaces which are used only during the day and require to be heated up to a working temperature each morning, the time required for this preliminary heating up will to a great extent depend upon the thickness and conductivity of the wall. In such cases the quantity of brickwork should be a minimum; 2½-in. brick backed up by 2½ in. of a good insulating material.

For large heat-treating furnaces which are working continuously the thickness of the wall should not be less than 13½ in.; a 9-in. course of firebrick, backed by a 4½-in. of insulating brick is good practice.

In general, in high-temperature wall construction, there are two separate and distinct factors which must be considered to produce an effective wall.

The first of these is to provide a material having the ability to resist the action of high temperatures, sufficient mechanical strength and, possibly, the property of resisting corrosive slags, gases, etc., without spalling or being eroded.

The second is to prevent the excessive loss of heat due to conduction from the interior of the wall to the outside, where it is lost by radiation or conduction.

It is rare that a good refractory material is an insulator; usually it is necessary to augment or back up the refractory with some material having a much lower heat-conducting capacity.

The following table gives a comparison of losses with insulated and uninsulated walls and various fuels which clearly shows how insulation increases efficiency:

FUEL LOSSES PER 1,000 SQ.FT. PER HOUR OF RADIATING SURFACE

Wall	Fuel	Loss per 1,000 Sq.Ft. per Hr. B.t.u.	Lb. Coal Loss per 1,000 Sq.Ft.	Gal. Oil Loss per 1,000 Sq.Ft.	Cu.Ft. Gas Loss per 1,000 Sq.Ft.	Calorific Value B.t.u.
Uninsulated	Coal	600,000	50.0	...	.....	12,000 per lb.
Insulated	Coal	220,000	18.3	...	.....	12,000 per lb.
Uninsulated	Oil	600,000	....	4.1	.....	145,000 per gal.
Insulated	Oil	220,000	....	1.5	.....	145,000 per gal.
Uninsulated	Gas	600,000	....	...	1,000	600 per cu.ft.
Insulated	Gas	220,000	....	...	366	600 per cu.ft.

Gas as a Source of Energy For Industrial Processes

Gaseous Fuel Not Only Gives the Highest Thermal Efficiency but Also Gives Opportunities for Increased Production Efficiency — Examples From Industry — Prospects for a More Extended Use of Gas as an Industrial Fuel

By Carl J. Wright
Technologist, Combustion Utilities Corporation

GAS, the ideal fuel, lends itself admirably to a program of increased efficiency in industry. When we think of efficiency in connection with a fuel we generally limit ourselves to thermal efficiency, or the ratio of heat output to heat input, but the subject may also be considered from the broader viewpoint of economy of natural resources and of human energy. As an industrial fuel it not only gives increased thermal efficiency, but in most cases gives increased quantity and better quality of product. It makes a clean workroom for the employees, and for this reason they are not only more contented but are healthier and can turn out better work.

Inasmuch as any fuel must be gasified before its heat energy is available, it seems logical that the fuel which is gaseous to begin with should be best adapted to give high efficiencies and close temperature control. Many industries today depend almost entirely on gas for their fuel requirements, and more and more industries are trying gas on operations heretofore carried on with some other form of fuel and are finding not only increased thermal efficiency but an increase in the quantity and quality of their product.

It should be understood that all gases are not equally efficient for all operations, but with the wide range of gases available for industrial uses it is possible to choose the kind of gas which has the proper characteristics for carrying on the heating operations in almost any industry.

Examples From Industry

The glass industry in the United States may be cited as an example of an industry which depends almost exclusively on gas as a fuel. In the early days of the industry it was thought that natural gas was essential for heating operations, and glass plants were built near each source of supply of natural gas as it was discovered. But as the natural gas fields became depleted and the demand for this gas as a domestic fuel increased it was necessary for many of the glass plants to look to some form of manufactured gas as a source of fuel. Today we find glass plants using various forms of producer gas, blue water gas, coke-oven gas, and in some cases the city gas which has been manufactured for domestic use. In all cases where they have given proper attention to furnace design and technical control of combustion they have increased the thermal efficiency of their operation and are turning out an improved product.

Several industries have found it highly advantageous to use gas as a source of heat energy in operations where temperature control and furnace atmosphere are important factors. For example, plants making porcelain enameled ware have found that they must have close control on both the furnace atmosphere and the temperature of the working chamber and they have found that gaseous fuels meet both of these requirements. For this operation the furnace atmosphere must be oxidizing and must have no carbon monoxide present otherwise a smooth finish will not be obtained. For solid- or liquid-fired furnaces it is generally necessary to inclose the working chamber entirely so that the products of combustion cannot come in contact with the work. This results in very low thermal efficiency because all the heat must be transferred through heavy refractory walls. Then too, the temperature within the muffle is not uniform, therefore a full load cannot be put in the muffle or some of the product will be second quality product. With gas, a semi-muffle or direct-fired furnace can be used. High thermal efficiencies are obtained and much more first quality material is turned out daily per furnace.

Gas as Fuel in the Metal Industries

Another operation in which the furnace atmosphere is very important is the melting of non-ferrous metals. Unless the atmosphere in the melting chamber is neutral, the metal losses will be high, and this metal loss must be charged to the fuel used. Gas and air can be mixed in very exact proportions, hence it is quite easy to control the furnace atmosphere with gas-fired furnaces so that a neutral atmosphere results. In fact, the kind of fuel used may affect all the subsequent foundry operations. In practice it has been found that metal melted in gas-fired furnaces will meet the strictest specification. At the same time these furnaces give good thermal efficiencies, low melting losses, high production per furnace and a clean, comfortable workroom. In crucible furnaces, longer crucible life is obtained with gas than with any other fuel.

The metal products industries offer numerous examples of the use of gas for heating operations, and in nearly every case the adoption of this form of fuel has resulted in higher thermal efficiency, better products and better working conditions. In annealing and heat-treating furnaces where gaseous fuels are used it is possible to have an absolutely uniform temperature throughout the whole working chamber, and this temperature can be automatically controlled; also it is possible to control the furnace atmosphere so that the material is not scaled. In heat-treating large guns gas has competed with electricity and oil, and it has shown a marked superiority in many cases.

Another use of gas in industry which is interesting and in which a superior product is obtained is in the carburizing of steel. In this case the gas is used as a carburizing agent as well as for fuel. The material to be treated is placed in a closed container and put in the furnace. A small stream of gas, rich in hydrocarbons, is admitted to the container. At this temperature the gas decomposes and the carbon is readily absorbed by the steel. The residual gas is returned to

e furnace burners and makes up part of the required el for the operation. Thus it is seen that the use city gas for this purpose eliminates the use of com-unds, packing, metal boxes and considerable labor. he parts to be treated come up to temperature uni-rmly and an excellent "case" is obtained. Another ing possible with gas and not with solid carburizing mpounds is the production of a diffused "case" which obtained by turning the carburizing circuit of gas f several hours before removing the material from e furnace. By this method an excellent "case" which ends with the core is obtained.

Some Other Economies Resulting From Use of Gas as Fuel

Many engineers believe that the day is not far dis-nt when the majority of all heating operations will e carried on by gaseous fuel, even to the extent of sing gas for firing boilers. And we may even see the me when gas will be a source of power for industry rough the medium of improved internal combustion gines. This is already done in those industries which roduce gas as a byproduct, notably the steel indust-y; r in such cases the gas would be largely wasted if it ere not so used and so its use even with inefficient gines is clear gain.

If gas is adopted as a universal source of fuel energy, ere are a large number of factors which will effect onomies of both natural resources and human energy. the atmosphere surrounding our cities and industrial nters were free from smoke, as it would be if gas ere used for fuel, much less artificial light would have be used. This not only gives a direct saving in the st of lighting but the workmen are able to produce ore and better work. Another economy which would e apparent is the saving in cost of cleaning and re-corating our buildings. This cost is due almost en-rely to the smoke and soot which is thrown into the mosphere during the combustion of solid and liquid els. If no solid or liquid fuels were burned in our ties, we would notice enormous savings in laundry lls and savings in cost of wearing apparel due to the ct that our clothes would not have to be washed so requently or so vigorously. In addition, the burden f the housewife in keeping her house clean would be aterially reduced.

Another item which should not be overlooked is that, the burning of raw coal, most of the valuable conden-ble products—particularly tar and ammonia—are lost. portion of these products is burned and some heat nergy is obtained, but these products would be many mes more valuable for other purposes than they are r fuel. Far-seeing fuel engineers are of the opinion at it will not be many years before industries in the nited States will be compelled, not only by economic ws but also by federal legislation, so to process their w coal that all these valuable byproducts will be re-vered. Some are even advocating the conversion of l coal into gas and condensible products at the mine nd transporting the gas to the cities and industrial nters through high-pressure pipe lines, to take care f the entire heating requirements of the community. Whatever may come of these larger visions, there still emains immediately at hand the direct advantage in roduction efficiency from wider use of gaseous fuels s the source of energy for industrial processes.

New York, N. Y.

Building the Plant Around the Transportation System

Production has in the past been generally considered as largely a matter of management. Today, in most chemical plants, the speed and efficiency at which men work is a matter of human control; and the efficiency of the plant is therefore a variable quantity—one impossible to forecast—and the difficulties of successful operation are manifold.

That this condition need not always maintain is the discovery of the last few years, particularly in the field of metal working. What is successful there can be applied at least in part in chemical industry. To illustrate what is meant, we quote the following from the August, 1922, issue of *Industrial Management* on the subject of the Ford plant at River Rouge:

Solving the Management Problem

"Even the major problems of management, strange as it may seem, have been solved at this plant by machinery and engineering. The 22,000 workers at River Rouge require an astonishingly small amount of supervision. Clerical and administrative labor has been reduced to an almost unbelievable minimum. Routing and dispatching are handled as engineering rather than as management problems; and solved by machinery, through transportation, rather than by management through supervision. Stock-keeping presents no unsolved problems, because the various processes, from the ore pile to the finished tractor on its freight car, have been mechanically timed to such a degree that production is a continuous flow without the need of stock reserves.

"Management difficulties that force themselves to the foreground at the average plant are non-existent or at least invisible at River Rouge. Ford and his engineers have made sure that the big basic principles are right and stay right so that details that would otherwise annoy and perplex seem to arrange themselves without obvious effort.

A Complete Industrial Chain

"Aside from all this, the River Rouge plant is of absorbing interest as a unique example of a substantially complete industrial economic chain. Ore from the Ford iron mines hauled on Ford's railroad is converted into pig at the Ford blast furnace and made into castings at the Ford foundry. Coke for foundry and blast-furnace use is produced at the Ford coke ovens. Gas for steam-electric power production, ammonia, distillates, tar and illuminating gas are produced at the Ford byproduct house and gas house. All of these units in the industrial chain are geared up as one complete machine.

The Conveying Equipment Is the Heart of the Organization

"Mechanical transportation forms the links which unite these separate units and their parts into one smooth-working, continuous process. Starting with the cranes which unload the raw materials, through the interplant conveyors that feed product parts, fuel and supplies in continuous, co-ordinated streams, everything is kept moving—by machinery. The spirit of the plant impresses the observer as an allegorical picture—a picture of engineering genius wrestling with time, for the prize of accomplishment."

Relation of Health and Happiness of Employees To Production in Industry

In This Article the Author Has Tried to Bring Out the Important Fact That Industrial Managers Should Give as Much Time and Study to Human Problems as They Give to Physical and Technical Problems of Production

By John S. Shaw
Hercules Powder Company

HEALTH: "A condition of soundness of any living organism, that state in which all the natural functions are performed freely, without pain or disease; freedom from sickness or decay."

HAPPINESS: "The pleasurable experience that springs from possession of good, the gratification of noble desires; the relief from pain or evil; enjoyment."

These definitions cover two human conditions which concern us very deeply. Much has been said and done to demonstrate the direct relation existing between man's health and happiness and his efficiency. During the years following the Civil War, and up to the present, the race for industrial supremacy has been keen and competition has extended around the globe. Leaders have toiled through a maze of factory problems, primarily leading to greater production, satisfactory quality and lower costs.

When considering these problems they naturally have concentrated on various processes, both mechanical and chemical, and on machinery or equipment in their plants. At the same time they have paid too little attention to the human side of the problem, taking for granted, more or less, that as long as men are paid the prevailing wages of their neighborhoods or calling, they should be thoroughly content to toil day after day, with no other inducement than that of earning their livelihood.

No doubt we all have experienced the fatigue due to monotony, which is a far more serious condition to humans than the mere physical or muscular fatigue. This may be explained by pointing out certain men whom we have known whose earnings are well above their standards of living, but at the same time those men are not contented, even granting that they may be healthy. Many such men do not know the cause of their discontent. They know that they are not satisfied. They will admit that they are restless, and they will seek higher wages, believing that the cause of dissatisfaction is insufficient money compensation.

In general we workers base our needs upon daily occurrences and environment, and fail to think out a clear and possible means of arriving at the greatest common good to all. The worker constantly wonders, "How much pay can I get for the least possible work?" while the employer is thinking, "How much production can I get for the wages I pay?" and the public criticises both and complains of the high cost of living.

What Is Needed to Insure Health and Happiness?

What is needed to insure health and happiness of our employees and a stronger and safer development of industry? Is it a method, preventive measure, or a cure?

Management really has two sides which should be equally developed and balanced—one the administration of production, the other the administration of those who toil and actually produce with their brains and hands. There should be no line drawn between the two, but they should be in separate departments and each equally a half of the administrative whole.

Production and costs depend absolutely upon huma efficiency and, as human efficiency depends upon th health and happiness of all of us, it is obvious that an action tending to promote health and happiness wi directly affect production and costs and greatly benef society.

Health

Before undertaking any great and important worl the worker should be in good health. He should hav complete control of all his physical faculties with th slightest amount of effort. His environment must en brace clean living, sufficient nourishment, good housin and pleasant surroundings, in order that his body ma be "in that state in which all the natural function are performed freely, without pain or disease." Healt is the foundation of happiness, for we all know ho little enjoyment there is in life to the physical sufferer The employer should see that his workers are enjoyin proper living conditions. He may have direct influenc over this through the control of "company houses" if not, he will have to make an effort to persuade an influence his workers to create proper homes from thei earnings. A good manager will go as far as assistin the employees to move to desirable and better homes.

Medical and Hospital Service

If the organization is sufficiently large to warrant company doctor and hospital, they should be employed It is strange to note that there are still many employ ers today who doubt the benefits derived from medica and hospital service to their employees. They believ that this is a delicate matter and is more or less tres passing upon the privacy of the employee to seem t thrust such service upon him. In answer to this, I ca say only that there are many instances where we owe i to the employees as well as the stockholders to see tha our employees are protected from the spread of diseas among their fellows.

Some employers also believe that the only purpose o medical service is to avoid the employment of th physically unfit who may make the unjust claim tha an injury or disease occurred after employment. Th matter of medical service is, therefore, regarded in th light of a gamble by some employers, who depend upo observations of their foremen to detect physical weak ness or disease. Unfortunately this belief may resul in very serious injury to both employer and employee The latter may unknowingly undertake work for whic he is unfit and, in consequence, become ill or injured t the extent of loss to himself and employer; to the em ployee through decreased earnings and suffering to him self and family and to the employer through risk o health and safety of his organization and lowered effi ciency and increased labor turnover. Health is th greatest capital man has. Without it the best of brain may fail.

For those organizations which are too small to affor medical and hospital service to the employees, I woul

iggest the employment of a physician for a certain our or two of each workday, during which time em-loyees requiring medical service may call upon the octor and receive the benefit of his care and advice.

Safety

A good live program of safety should be carried out. ire and accident prevention are not only humane un-ertakings, but are of great economic importance. Most mployers have found this to be true, and it is gratify-ig to see the great progress that safety work has ade. There is another real reason for safety work—amely, the psychological effect upon the help. Instead f fear of death and injury, the worker's confidence is ncreased and hence the contribution to his happiness. he most successful safety work is noticed in factories here the help are all given an equal chance to make ggestions to a committee appointed by themselves and uided by wise management.

Happiness

Creative Impulse

Isn't it surprising how many schemes and methods re in practice today under the name of scientific man-gement? We have anything from employees' repre-ntation to profit sharing. The magazines and books re full of such ideas, but very few speak of the key the worker's real happiness—viz., the instinct of orkmanship, or the creative impulse. The desire to be reative is fundamental in human nature and failure find an outlet for self-expression results in serious ifficulties. Suppression of this basic natural tendency potentially disastrous. The task of the management hould really be to find some positive and constructive utlet.

A few men in our country have practically spent their ves endeavoring to solve the problems from the human de, and since the great war the mysterious "personnel epartment" has sprung into greater prominence. Tead nd Metcalf describe personnel administration as directing and co-ordinating human relations of any rganization, with a view to getting the maximum neces-ary production with a minimum of effort and friction nd with proper regard for the genuine well being of ie workers." Notice there is not in this definition a ngle word mentioning costs! In their splendid book ntitled "Personnel Administration" they cover the sub-ct in a remarkable and interesting way.

R. B. Wolf, industrial engineer, of New York City, as spent the last 20 years seeking out the healthful nd happy way for workers to pursue their labors. oday he is one of the foremost managers and authors nnected with industry, and while he is thoroughly ractical and realizes the importance of low costs, the ain theme of his work is "non-financial incentives" and e appeal to the creative impulse of man. So import-nt does Alfred Korzybski consider the freedom of is expression that he attributes not only restlessness the individual but wars of nations to the suppression the creative impulse, or the "instinct of work-anship."

First of all, man seeks work because he must be othed, fed and housed. He goes to work and is given hat appears to be a fair wage. He may set a pace to e machine he operates, or that contrivance may be a ce setter to him. He does the same thing over and er every day in the same way and draws his pay om week to week with the same dumb monotony. He sees others enjoying more comforts than himself and he strives for those pleasures, comforts and perhaps luxuries, or, better still, he desires to possess his own home where the love of a wife and children control the center of his ambitions.

At this point, if his employer takes an interest in him, gives him a little encouragement and explains the why and wherefore of his job and the nature of the service rendered to the public through his labors, there is not much danger ahead. If he is permitted the full exercise of the creative impulse, given proper guidance and credit for his fruitful efforts, he is bound to be content. In order to accomplish this, a proper system of records and charts should be kept before the workers. Every one likes to watch a scoreboard, no matter what the game. Friendly competition is a stimulant to man's incentive. Here's where the love of creation comes in. After all isn't it something divine in man? His love of accomplishment and desire for approval are real forms of human expression. This desire is often obscured by more immediate claims and sometimes little appreciated because of the paralyzing effects of fear.

The problem, then, is to permit men working in groups to retain their individuality and for each man to feel that he is an independent human being, striving toward a definite goal to be attained only by his individual effort. To make him see that co-operation with fellow employees and his employer is the best means of attaining true individuality and self-assertion is difficult, but this can be accomplished by the principles involved. It is obvious that as the understanding of individual obligation spreads so as to include groups, a tremendous source of human energy and power which is now little understood will be made available to society.

Religion

Good "old-fashioned religion" is not to be considered too lightly. Co-operation with the religious teachers means fellowship, co-operation and an honest striving of the masses for service and common good. If a man is suppressed in or discouraged from progressing along proper lines, immediately there is trouble ahead. Selfishness and jealousy kindle and trouble brews from worker to worker, while the thoughtless manager schemes on his production and costs.

What then is meant by "proper guidance"? For instance, right now we believe that we are facing a long period of deflation. Wage cuts are in vogue and if history is to repeat itself labor will be sullen for some time to come. As the value of the dollar rises, the amount of money earned must necessarily become less and less. Such a condition should be frankly and sincerely explained and discussed with the men.

Representation of Employees and Personal Contact

In small organizations I suppose it has been recognized since before the day of Moses that personal, friendly contact with the toilers is the greatest salvation to enterprise. There is little trouble in factories or shops where the boss knows all the men and they have confidence in him. In larger organizations, say over 500 employees, where the boss is too busy to keep up his acquaintance with every one of his workers, and while he is engaged in his problems which keep him in his office a great deal of his time, there is a tendency for the value of contact to be forgotten and the kind and sympathetic policy of even the greatest hearted leaders fades out before it reaches far down the line in the organization.

If this condition exists, it would seem that a proper time should be set aside for the meeting of representatives of the employees, at which time the management will give their full time and attention to the desires and suggestions of the workers. All men can reason and most men are honest. If a request or suggestion be not granted the workers, they should be thoroughly satisfied with the reason and mutual agreement enjoyed by both sides. A great deal of time has been spent as a result of plant managers attempting to give employees what they think they should have instead of finding out in an open meeting—through free expression of employees—what they really want. It requires sincerity and frankness to point the way, so that men may enjoy freedom of expression, proper guidance and square treatment.

Progress

We all know what it is to feel the joy of progress. But because of the competitive state of industry, there is a limit to wages that may be paid. Consequently we should not relax in our effort to keep up interest among the workers by training them more and more in their work, promoting them when we can and, when we find our organization too small, going to the extent of helping them get larger positions with other employers. The incentive given the workers in any organization through this policy is great and more than compensates for the loss of a valuable employee occasionally. Then every worker will feel that if he reaches his limit in the organization he is still preparing himself for a greater reward elsewhere, and that the boss will be glad to say a good word for him, and in fact help him to obtain a better job.

Recreation

Pleasure during leisure hours is very important, and a little effort on the employer's part to put system into leisure is a very valuable thing. When the tension of work has ceased at the end of the day, the worker is naturally restless but happily in a receptive mood where pleasure is concerned, and at this moment we should endeavor to meet him and fulfill his want and give him legitimate opportunities for wholesome pastime. This may be accomplished by seeking out a few well-known and trusted employees and asking them to form a committee which will nominate officers among the help, in an open meeting, to serve on a recreational board. When this board is elected by the employees, it should be understood by all that the management shall at all times maintain the power of veto whenever it is found necessary to use it, or to maintain order and to prevent unreasonable expense. There are many forms of entertainment which by the aid of both men and women of the plant are readily worked out.

Pride of Possession

History seems to indicate that those people who own their homes or possess land are the least apt to rebel against their governments. We know that the man who is interested in his home is happy, and I believe the time is coming when industrial workers will be encouraged more and more to own their homes. It is certainly a stabilizer, for men will stop to reason when something they hold dear is at stake. Employers are realizing this and are assisting their help in purchasing their homes or by fostering some sort of thrift plan which leads to saving and financial independence.

So far we have considered the matter of honest, sympathetic and wise management of the worker and h health and happiness during work and recreation, b there is still another great power to reckon with f the building up of happier relations and a sympathet understanding between worker and manager, and th is the pride of ownership in the enterprise.

Thrift Plans

Stock subscriptions on easy term payment plans a in proper proportion to the worker's wages have in proved workers and employers alike. It is a foolish ma who tears down that which he builds himself, a dividends paid to stockholding employees have a marke effect in establishing contentment and understandin We shall hear less about "capital and labor" when mo of us who labor are "capitalists" too. The worker wh owns stock in his company soon learns that witho capital there is no labor or vice versa; that each is a equal half of the whole, that one cannot exist witho the other.

The world is getting better. Men are thinking mo of the general welfare of the race than ever befor There is more real honest effort to be frank and hones with each other, and, in spite of the present turmoil an severe loss of time and production due to strikes an their causes, men are drawing nearer the solutio Selfishness is slowly but steadily giving way to justic and it will not be many years before unjust demand will be met by such strong public disapproval tha men will strive harder and more unselfishly to co-ope ate. No profit will be considered worthy or gratifyin unless it is earned through fair service to investo toiler and the public alike. Progressive business me are accepting the belief that this is good business.

There are still too many fault finders instead of fac finders. We should remember that the procedure is after all, a simple one based upon justice, commo sense, perseverance and an abundance of patience.

Wilmington, Del.

Safety Organizations as an Aid to Health and Happiness of Employees

Harry A. Schultz, assistant manager of the bureau o safety, sanitation and welfare, U. S. Steel Corporation has published an article in *Safety* for August in whic he describes some of the functions of the safety organization. One thing stands out in the article. It is th tremendous aid which a safety campaign can be toward furthering the health and happiness of the employees not only the actual diminution of injury and conse quent gain to the organization but the mental relie which comes to the worker when he realizes that a honest, intelligent effort is being made to protect his interests and his health. Workers are quick to see through subterfuge. They realize immediately when an attitude is sincere and when it is camouflage.

Another point which Mr. Schultz mentions has to d with stimulation of the safety spirit. An obviously guarded machine is a distinct asset to shop morale.

Educational activity in connection with safety campaigns is another phase of work which must be very carefully tuned to workers' psychology. Straightforward honest substance must be the backbone. A splendid example of failure in such a campaign was a Americanization campaign carried out in many industrial plants and an equally splendid example of success is the safety poster campaign which runs continuously as a service.

Standardization Will Increase the Production Efficiency of the Chemical Industries

THE industrial significance of standardization has been ably defined by Dr. P. G. Agnew, secretary of the American Engineering Standards Committee, in a platform of sixteen points, seven of which pertain directly to increased production efficiency. These seven points are as follows:

Standardization stabilizes production and employment.

Standardization makes mass production possible.

Standardization eliminates indecision in production.

By concentrating on fewer lines, standardization enables the manufacturer to put more thought and energy into designs.

By bringing out new facts in order to determine what is best and to obtain agreement on most questions, standardization acts as a powerful stimulus to research and development.

Standardization is one of the principal means of getting the results of research and development into actual use in the industries.

Standardization helps to eliminate practices which are merely the result of accident or tradition and which impede development.

These are some of the things that standardization will do for industry in general, and there is no real reason why it will not do as much for the chemical industries.

Present Status of Standardization in Chemical Industry

To judge from the experience of other industries, such as those in the electrical and automobile fields, it would seem probable that standardization will proceed slowly in the chemical industries during the next few years, after which it will go forward on an increasing scale and with increasing rapidity. There is no doubt that if standards are agreed on properly by producers and consumers, they will come into as general use and be of as great advantage in the chemical field as elsewhere.

A great deal of valuable standardization work has already been accomplished in many of the chemical industries. Consider a few examples: In the fertilizer field there has been extensive work done in the standardization of grades. This has been worked out by cooperation between producer and consumer. In the paint and varnish field a great deal has been done in defining materials and in agreement on methods of test. Cement is in excellent shape; better, in fact, than most other industries. This results from the fact that the American Society for Testing Materials and the various governmental bodies concerned finally settled on specifications. These are now universally recognized as a real national standard. In rubber comparatively little has been done.

Standardization Work by Technical Societies

The American Chemical Society has had, for many years, a supervisory committee on methods of analysis which has done work of far-reaching consequence. The work of this committee has been of considerable help to other societies engaged in standardization.

A well-known example is the valuable contribution of the Manufacturing Chemists' Association to the movement through the standardization of the Baumé table for determining the specific gravity of liquids. It was not so long ago that there were in use in America twenty-three different variations of the Baumé scale. The result, of course, was infinite confusion. Today there is one Baumé scale in use throughout the United States; a fine example of increasing production efficiency through standardization.

Need for Inernational Standardization

The Baumé scale used in America, however, is not the Baumé scale used in Germany. This brings us to the need for international standardization. In America 66 deg. Bé. indicates 93.5 per cent sulphuric acid; in Germany 66 Bé. indicates 98 per cent sulphuric acid. There are cases where 98 per cent is effective and 93.5 per cent no better than water. Yet there are in America hundreds of students and others reading German literature on the subject, conducting experiments and carrying on research without realizing this difference in the Baumé scales of the two countries. In England there is still another scale, called "Twaddell" after the man who devised it, but it is not used in America.

Standardization of Nomenclature

If we are to increase our production efficiency, we must first of all learn to talk the same language. In other words, a prerequisite to increased production efficiency in the chemical and metallurgical industries is, as in other fields, the standardization of nomenclature. If we are to have increased production efficiency, we must first settle on definitions. Sulphuric acid, for instance, should always be designated in terms of SO_3, sulphuric anhydride, which is common to all strengths of acids. In one large American company all sulphuric acid accounts are kept in terms of SO_3, and as a result this company knows immediately the cost of any strength it needs. It is difficult to understand how the manufacturer who does not keep his sulphuric acid accounts on this basis can know what he is about in handling sulphuric acids. Yet there are few manufacturers in America who observe one standard in their records.

Standardization of Equipment

There is a tremendous opportunity in the chemical and metallurgical industries for the standardization of apparatus, tools and other mechanical equipment. In this work the chemically controlled industry appears as the ultimate consumer, instead of as a producer, its rôle in the case of materials.

Work of the A.E.S.C.

The standardization that has already been effected has been possible only because the producers, consumers and general interests were brought together. The necessity of this has been shown over and over again in the experience of those bodies which have done extensive standardization work. It often happens that before agreements can be reached the air has to be cleared of misunderstandings through disagreements and controversies, not to say fights, that have sometimes lasted for

years. Yet when these differences have been thoroughly threshed out, results of great value are almost sure to ensue. The development of the whole co-operative idea in industry has brought about the possibility of systematic co-operation in standardization work on the part of the various bodies which speak for industry, and the American Engineering Standards Committee has been developed as the mechanism of this systematic co-operation. Conversely, the very existence of the A.E.S.C. has stimulated industrial co-operation in standardization by those interested.

Standards Now Being Considered

Many of the men who are most active in the affairs of the A.E.S.C. are identified with the chemical industries or the profession, and at least fifteen of the eighty projects now under consideration are of direct interest to the chemical and metallurgical industries. This list includes the following:

Chemical analysis of alloys of lead, tin, antimony and copper.
Electrical properties of aluminum.
Standard methods of laboratory sampling and analysis of coke.
Safety code for explosives.
Specifications for galvanizing and sherardizing iron and steel.
Gas safety code.
Standard specifications for purity of linseed oil from North American seed.
Paper and pulp mills safety code.
Standard method of test for penetration of bituminous materials.
Pipe flanges and fittings.
Color schemes for pipe lines.
Safety code for tanneries.
Safety code on ventilation.
Zinc and zinc ores.

Standards Already Adopted

Nine standards of a chemical nature have already been approved:

Specifications and tests for portland cement.
Standard method for distillation of bituminous materials suitable for road treatment.
Standard method for sampling of coal.
Specifications for lake copper wire bars, cakes, slabs, billets, ingots and ingot bars.
Specifications for electrolytic copper wire bars, cakes, slabs, billets, ingots and ingot bars.
Methods for battery assay of copper.
Methods of chemical analysis of manganese bronze.
Methods of chemical analysis of gun metal.
Specifications for the testing and use of permissible explosives.

What Standardization Will Do For Industry

Standardization is merely getting together and agreeing. Among the important things which standardization will do for the chemically controlled industries are:

It will provide a more truly competitive market in which to buy equipment.

It will make it easier to repair and replace chemical manufacturing equipment.

It will reduce the cost of manufacture.

It will simplify the keeping of cost accounts.

It will eliminate most of the controversies as to whether the product is in accord with the sample.

It will increase the production efficiency of the industry.

It will give accurate definitions to enable one to know what he is talking about, what he is buying and whether he is getting what he is buying. Such definitions will go far to eliminate disputes and litigation.

Standardization of Shipping Containers

One of the most important phases of the standardiza tion campaign is that which looks toward the adoptic of standard, efficient and simple containers for shippin purposes.

At the recent meeting of the American Society fc Testing Materials a committee report was presented o this subject which shows the progress which has bee realized in the campaign for such containers.

Work by the A.R.A.

The importance of determining what shipping co tainers are proper and efficient and of prescribing cle and definite specifications for them has been recentl recognized in a very active manner by the America Railway Association. The executive committee of tha association, in connection with its drive to reduce los and damage, has ordered the bureau of explosives t expand its test and specification department to includ the investigation of shipping containers for all kinds c commodities and to prepare recommendations in th form of specifications for the efficient container.

The freight container bureau is investigating shi ping containers from a purely engineering standpoin which will, of course, involve special consideration o proper economies and the standardization of types a well as the actual efficiency of construction for trans portation purposes. Investigations are being made a plants making the containers and at plants using them shipments are also to be followed and observed at rail way stations and steamship piers to determine actua results in transit.

Reasons for Container Standardization Found Within the Plant

In addition to the economies and advantages to b realized in rail and water shipments through the adop tion of simple and standard containers, the use of thes containers aids greatly in the efficient operation of th manufacturing plant itself.

Containers must be either purchased or made in th plant, and, in either case, the fewer the types used an the more nearly uniform these types are, the less spac is required for their storage. If the containers ar made in the plant, then the parts or the material fron which they are made will be received in an unworke state. In this case, the labor cost of working thi material up into the desired form is reduced in pro portions as the number of styles and sizes of container is reduced.

The Standard Container and Automatic Equipment

To realize, in any industry, the maximum efficiency of production, we must resort to the fullest possible extent to the use of automatic and labor-saving equipment. This applies possibly more to packing and shipping the product than to any other operations which it undergoes. It will be readily recognized that wrapping and filling equipment can be applied to only a limited range of container sizes. So also, conveying equipment is limited as to the types of container which can be handled. Thus unless a plant is to have a multiplicity of this automatic equipment, much of it idle at any given time, or is to do without realizing the full advantages of this equipment, it becomes necessary to confine the containers used to the smallest number of simple types which ingenuity can devise.

Manufactured Weather And Personal Efficiency

An Analysis of the Advantages Which Accrue From the Use of Humidified Air-Ventilating Systems — Especially With Reference to the Efficiency of the Individual Worker

By Willis H. Carrier
President, The Carrier Engineering Co.

IN MANY industries the modern science of air conditioning is employed effectively to increase the process efficiency where products sensitive to atmospheric temperature and moisture are involved. The idea of manufacturing weather to meet the requirements of the many industries manufacturing such products is already firmly implanted in the minds of the great manufacturers of this country. In fact, manufactured weather, made to meet the exact requirements of these industries, has so improved their process efficiency that the manufacture of such products as cotton, wool, silk and other textiles, tobacco, candy and bakery products may be said, without exaggeration, to have been revolutionized by the application of scientific air conditioning.

It seems, therefore, quite astonishing that a conception of personal efficiency, as affected by the physical condition of the worker, has not developed coincidentally with our intense development of process efficiency. It is true that in the modern plant the physical comfort of the employees is most carefully considered with respect to sanitation, seating, lighting and arrangement of equipment to minimize the effort necessary to the given operation. But in only a few of our modern plants have the effects of the condition of the surrounding atmosphere been considered.

Elements of Production Cost

There are three elements of production recognized as determining the profits of a manufacturing process:

1. The volume and value of the product produced for a given plant investment.
2. The quality and uniformity of the product produced.
3. The cost for labor per unit of production.

Even in cases where the product is of such nature that the first two of these factors are not involved, the third factor is so directly affected by the atmospheric conditions within the plant—that is, temperature, humidity and cleanliness of the air—that scientific air conditioning will prove an exceptionally profitable investment. Although it is true that in a surprisingly large number of industries the product itself or the process of its manufacture is directly affected by atmospheric conditions so that upon the basis of enhancement of process efficiency alone air conditioning pays handsome returns, it is the province of this paper to discuss primarily the effects of air conditions upon the human being as these effects are related to the personal efficiency of the worker.

No matter how highly mechanized the given industry may be, the quantity and quality of the product always depends, in large measure, upon the personal efficiency of the workers themselves. It is a well-recognized fact that the personal efficiency of the human being is seriously impaired when he or she is subjected to improper air conditions, such as excessive heat or cold, excessive humidity or dryness, or air that is contaminated with dust, fumes or other injurious impurities. Unhealthful and depressing air conditions are inherent in the manufacture of certain products, such as the excessive heat caused by the power utilized in a large textile mill, the fumes in a chemical plant and the dust in a tobacco factory.

In most of these industries the condition is so acute that it has received the attention of employers by force of necessity. In many other industries where the condition is of lesser degree, the impairment of personal efficiency is scarcely the less serious and the question of providing healthful and invigorating air conditions is of great importance.

Conditioned Factories Capable of Holding Workers

There are, in fact, many instances where the personal efficiency of the workers themselves has proved of greater moment than the mere mechanical efficiency of the process. In any industrial community where there is broad opportunity of choice in employment, workers will seek employment where conditions in respect to health and comfort are most satisfactory, assuming that wages are approximately equal. This is particularly true of female workers, a great many of whom are willing to accept work where the factory conditions are good and the environment proper, but who would not work, unless compelled, under unhealthful or distasteful conditions.

Thus one of the first direct results of improving the atmospheric conditions within any manufacturing plant is the attraction of a labor supply which is satisfactory in both quantity and quality, permitting the selection of more efficient workers at a reasonable wage. In addition there is a correspondingly lower labor turnover because the employees are satisfied and anxious to retain their positions in the plant where healthful and invigorating conditions are assured by the installation of well-engineered air-conditioning equipment, the labor problem is greatly simplified and it is possible to develop a carefully selected personnel, so that the common dissatisfactions are practically eliminated, the turnover is minimized and there is little necessity for discharge and replacement.

Analysis of labor cost by Mr. Alexander of the General Electric Co. has shown that the cost of losing one worker and replacing him with another amounts, both directly and indirectly, to from $50 to $250, depending upon the skill and experience involved. A low labor turnover and satisfied employees are, therefore, exceedingly important elements in the cost of production. Before discussing the importance of proper air conditions, let us examine the factors which are involved and the conditions conducive to health and vigor, or, in other words, to personal efficiency.

The problem of the air-conditioning engineer is divided into two distinct phases—that is, conditioning in the winter and in the summer. In winter there are

two principal factors: the uniform heating of the inclosed space to a definite controlled temperature, and the addition of sufficient moisture to supply the deficiency in outdoor winter air which has been heated to ordinary indoor temperatures. For example, outdoor air at zero, assuming it to be fully saturated, will contain less than one-half of 1 grain of moisture per cubic foot. This air when heated to 70 deg. requires, to saturate it, 8 grains of water vapor per cubic foot. Thus the relative humidity of zero outdoor air heated to 70 deg. indoors by any of the common methods of heating, such as the steam or hot water radiator, which do not add appreciable quantities of vapor to the air, would be approximately 6¼ per cent, since the air would contain but one-sixteenth of the moisture which it could contain at its new temperature. Thus such air would be so excessively dry that it would exert an intense drying effect upon the skin and the delicate mucus membranes of the noses and throats of the workers. Such a condition inevitably produces a severe physical depression in the worker and an accompanying mental depression which are reflected in a dullness which in turn seriously impairs the personal efficiency of the worker from the production standpoint. Further, such a condition is conducive to colds, bronchitis and similar ailments which cause a high rate of absenteeism and a consequent decrease in production, together with an increase in production cost.

A suitable air-conditioning equipment will relieve such conditions of excessive dryness in closed buildings, under winter conditions, by automatically humidifying the air to that percentage of relative humidity most conducive to health and vigor. In addition, such equipment will afford a distribution of the conditioned air so uniform and so free from drafts that the general comfort and health of the worker will be enhanced.

Summer Ventilation

In the summer the problem is reversed. The presence of a large number of workers within an inclosed space, in conjunction with heat generated by power, lights and other causes, even if all of the ordinary means of natural ventilation, such as open doors and windows, are employed, will cause a vitiation of the atmosphere and an increase in temperature which will result in depression, dullness and loss of personal efficiency. It is well known that in many industries production, during the extreme heat of summer, will fall off as much as 25 per cent.

Dr. E. Vernon Hill of Chicago has made experiments indicating that the cooling effect or comfort condition of the air depends in a larger measure upon the wet bulb temperature than upon the dry bulb temperature. He found that the most comfortable wet bulb temperature under normal conditions is about 56 deg., although this point must be raised in summer time in order not to cause too great a contrast between outdoor and indoor conditions. He also determined approximately the relative effect of air velocity in producing a cooling effect. For example, we have all noticed the cooling effect of a draft of air or of an electric fan even though there was no actual change in temperature or moisture condition. This occurs because the air under velocity is capable of carrying away a greater amount of heat. Dr. Hill has related the wet bulb temperature and velocity conditions in so-called zones of comfort so that, with a given wet bulb temperature, the velocity required to insure comfort and health can be readily determined.

There are two methods by which the summer conditions can be relieved. In a building where there is a great inherent heat source, such as a textile mill where a great quantity of power is utilized, evaporative cooling may be employed. In this method all of the air enters the building through a humidifier which cools it to the outdoor wet bulb temperature* (usually from 10 to 25 deg. below the dry bulb temperature) and fully saturates it with water vapor, at the same time washing it clean and free from dust and other impurities.

The conditioned air, saturated at the outdoor wet bulb temperature, is then uniformly distributed throughout the building in such volume that the rise in temperature within the room is sufficient to depress the relative humidity to a comfortable degree, though the final temperature is an appreciable number of degrees below that of the outdoor dry bulb.

Thus, without the use of cold water or refrigeration, since the water of the humidifier is used over and over again, only that part absorbed by the air being replaced, it is possible to effect a comfortable and healthful condition within factories of certain types, in any locality. In localities where the wet bulb depression is normally very great, such as in our Middle Western states, it is possible to effect a sufficient degree of evaporative cooling even where there is no great internal heat source, the external heat being utilized to bring the air to that temperature at which its relative humidity is comfortable and invigorating.

If evaporative cooling, due to the locality, to the conditions within the plant or to the necessity of maintaining a temperature and humidity below those of the outdoor atmosphere, is impracticable, the cooling can be accomplished by the use of natural cold water from wells or other sources or by the use of mechanical refrigeration. By this method it is possible to maintain any required temperature and humidity regardless of the outdoor conditions.

Weather Can Be Manufactured Anywhere

Thus, no matter what the locality may be or the particular conditions within the given plant, air-conditioning equipment can be applied to establish and maintain whatever conditions of temperature and humidity are most desirable or warranted. It should be borne in mind, of course, that the factor of cleanliness, though not sufficiently stressed in this writing, is of great importance, and that all well-designed air-conditioning equipment provides air that is clean and pure whether the equipment be functioning to humidify or dehumidify.

The initial cost of adequate air-conditioning equipment, when considered on the basis of human efficiency and human comfort alone—that is, exclusive of process efficiency—often appears to be too high to permit consideration. This is because we are unaccustomed to consider human efficiency in terms of dollars and cents. The cost of any apparatus is not measured by the number of dollars and cents involved in its purchase, but by the number of dollars and cents which it can earn for its purchaser. When we have become accustomed to evaluating human efficiency in the same way in which we now evaluate the production efficiency of the machine, the cost of scientific air-conditioning equipment

*If partly saturated air is brought into contact with water, preferably in a finely divided state, and permitted to absorb sufficient water vapor to become saturated, it will be cooled to its wet bulb temperature.

will appear insignificant when compared with the results which it accomplishes.

Leading to the discussion of the effects of air conditioning upon labor it is worth pointing out that when labor is scarce in time of great industrial activity and a command of the labor market is of greatest importance, the condition plant invariably has first call and rarely is unable to fill all of its labor requirements.

The effect of improved atmospheric conditions upon employment may be typically illustrated by the case of a textile manufacturer in Fall River, Mass., who installed a ventilating, cooling and air-conditioning system in his new mill alongside a similar, older mill not thus equipped. All of the employees in the older mill applied for work in the new mill during the first summer of operation, during a time when there was great scarcity of labor. The manufacturer found it utterly impossible to get sufficient labor to run his unconditioned mill to full capacity and efficiency. At no time, however, did he have the slightest difficulty in getting all the labor needed in the conditioned mill. As a result the profits in the new mill during this period of activity greatly exceeded those of the older mill. Another thing that he noticed was the decreased labor turnover in the new mill as compared with the older mill. In fact, the demand for employment in the ventilated and cooled mill was so great that the management found it expedient to offer change of employment from the other mill to the new mill as a prize for exceptional proficiency as well as punctuality and attendance.

The manager of a large New England factory had been experiencing great difficulty during the hot summer weather in keeping the plant operating at capacity. The combined heat of a high outside temperature and the additional heat from the machinery was such that the girls in his employ were frequently taken ill during the day and the routine of the factory was seriously handicapped. The experience made him realize the importance of securing proper conditions, if possible, in his mills, and he made several attempts, with partial success, to improve the conditions. Finally he decided to install a modern ventilating and conditioning system in one of the smaller of his plants, with the result that the difficulties he had experienced in summer were entirely eliminated. This led him to equip all of his old factories, as well as those built later, with the same type of equipment, at great expense, the improvement in labor conditions alone warranting this procedure.

Tobacco Dust Settled and Prevented

Another concrete illustration is a tobacco factory in Richmond, Va., in which mechanical stemming machines are used to strip the leaves from the stem. The dust produced by this process was so great that one could not see the length of the room. Operators had to breathe through handkerchiefs placed over their mouths. As a result, it was found difficult to secure sufficient labor to keep all of the machines in operation and only the poorest class of labor could be obtained. The installation of an adequate humidifying system both settled the dust and largely prevented its formation, the working conditions became measurably ideal and no difficulty was experienced in getting the best type of labor to operate the plant at full capacity and at highest efficiency. Not only was the output of the plant increased, but the labor turnover and cost was reduced and the efficiency of the machines increased due to a better working condition of the tobacco. The annual saving in tobacco alone was more than sufficient to pay for the equipment, besides a material saving in the wear on the machines.

As an illustration of the desirability of properly conditioning the air of buildings in which the process itself is in no way affected, the Ford automobile plant in Detroit may be cited as a conspicuously successful example. Mr. Ford first had his office equipped with a modern ventilating, humidifying and cooling system, and the benefits from it were found to be so great during the hot summer weather that he decided that such a system would give equal or greater benefits throughout his entire machine shop. Elaborate ventilating and cooling systems of this character have now been installed throughout his plants and have become a standard feature of all new construction. The benefits derived are felt to be more than commensurate with the expense entailed.

Individual Efficiency Benefited

While the efficiency of an operator depends largely upon the individual, yet the same individual will do more and better work if in good health and working under conditions of physical comfort and mental contentment. Conditions of excessive dust, or conditions of extreme temperature and moisture, are injurious to health, thus lowering the vitality and driving force of the operative, without which he cannot accomplish the most and best work. He is apt to be frequently absent, due either to sickness or to desire for change. Even though atmospheric conditions may not be sufficiently bad to cause ill health, they may affect the comfort and mental state of the operative to such an extent as seriously to distract him from his work. Such conditions may only be seasonal, as, for example, in summer, while in other cases they may occur only in winter. In a textile mill that is insufficiently ventilated and cooled, the operators will be found opening the windows and spending most of their time standing near them, often to the neglect of their work. Such conditions result in a noticeable loss of production.

Where this condition has become customary, as in old plants, it is often found very difficult to prevent operatives from opening the windows after a cooling and humidifying system has been installed, even though the opening of the windows in no way improves the condition. This seems to be largely a psychological effect and in general it is desirable to provide such a form of ventilating and cooling system that the effect of opening the windows will not be especially detrimental to the operation of the system. In most plants it is desirable to arrange the lower portion of the sash so that it cannot be opened, with a ventilating sash provided in the upper part sufficient only for the exit of air from the building.

In many office buildings where ventilating and cooling systems have been installed, occupants still desire to open windows, although the effect is almost entirely psychological. This practice is not objectionable in summer except where there is a dehumidifying system installed to reduce the air to both a lower temperature and moisture content than that outside. Here it is essential to the efficient operation of the system that all the windows be closed. On this account it is necessary, with a system of dehumidification and cooling, that the temperature and humidity standards be established with due regard to personal comfort, so that there will be no desire to improve the ventilation.

The determination of those conditions of temperature

and humidity most comfortable and invigorating to the human being involves a study which has been prosecuted for many years. Investigations have been conducted by physicians and by engineers. Obviously it is not possible to establish any given condition of temperature and relative humidity as the most desirable, since there are many conditions of temperature and relative humidity—the relative humidity varying, of course, with the temperature—which are comfortable and stimulating. It is true also that indoor conditions which are comfortable in the winter would be extremely uncomfortable in the summer. Nature adapts our bodies to changing conditions with a remarkable facility. Everyone has noticed that in the late fall or first days of winter we are chilled by temperatures which later in the winter we resist without difficulty. It is notable too that the first very hot days of summer are much more depressing than the same conditions later in the summer when nature has adapted us to withstand the summer conditions. Most of us are accustomed to winter temperatures considerably higher than those which are most healthful. This is true because winter air heated to ordinary indoor temperature is excessively dry and does not afford the feeling of warmth, even at high temperatures, as much as 80 deg. F., which the same air would afford at much lower temperatures, as low as 68 deg. F., if the air were moistened to the proper percentage of relative humidity; in other words, 80 deg. air at a relative humidity of 20 to 25 per cent is far less "warm"—i.e., does not produce the sensation of warmth which air at 68 deg. and 50 to 55 per cent relative humidity affords.

The writer has repeatedly observed that individuals—women, for example—who habitually spend much of their time in winter in the home, require, if the air is dry or not humidified, extremely high dry bulb temperatures, even in excess of 80 deg., before they experience the feeling of warmth. Constant exposure to excessive dry bulb temperatures of this nature, the air being as dry as it normally is in an unconditioned building, induces mental and physical dullness and renders the subject highly susceptible to colds, bronchitis and similar ailments of the bronchial areas.

It is notable too that when exposed to high dry bulb temperatures at low relative humidities the human being is astonishingly susceptible to drafts. In very dry heated air nature attempts to protect the body by establishing a film of more moist air in immediate contact with the body. This is assisted by the clothing, which prevents the sudden dispersion of the film by drafts. Thus it is that the draft is most noticeable upon the unprotected skin or upon the ankles and lower limbs which are but scantily protected.

Low Humidity in Houses Is Barbarous

Humidification entirely relieves this unfortunate, indeed it may be characterized as barbarous, condition. The maintenance of a temperature of 68 deg. as a suitable relative humidity (from 45 to 55 deg.) affords complete comfort in stimulating both physical and mental vigor. The dollars and cents value of such stimulation in the case of the worker employed in productive effort, though difficult to compute precisely, is obviously very material.

In the summer, with the outdoor conditions reversed, a number of new factors are introduced. It is well known, of course, that the average person is rarely actually incapacitated by even unusually severe summer conditions, provided those conditions occur gradually, whereas it is equally well known that a sharp change either from hot, humid weather to cooler and less humid weather, or vice versa, will cause extreme discomfort even though the actual values of temperature and humidity in either case are not in themselves extreme or even ordinarily large.

Because of this inability to adapt ourselves to sudden changes in summer temperature, it is not feasible to establish in summer a fixed internal temperature and relative humidity to be maintained every day. It is necessary to establish internal conditions of both temperature and humidity which bear a definite relation to the external conditions. Thus, on a day when the outdoor temperature is 90 deg. and the relative humidity fairly high, the average person experiences a feeling of complete comfort and relief upon entering a building in which the temperature is 82 or 83 deg. and the relative humidity slightly depressed. Again, on a day of 80 deg. outdoor temperature, the relative humidity being high, as usually occurs in August in the climate of New York City, the internal condition of 74 or 75 deg., the relative humidity being materially depressed, affords complete comfort and is extremely invigorating.

Nature's Provision for Changes in Temperature

Because it may foster a more thorough understanding of the subject, it may be well to point out that nature attempts to compensate for excessive summer temperatures by increasing the rate of evaporation from the skin, and thereby affords the body the relief of the consequent evaporative cooling. If the humidity is high, the rate of evaporation is correspondingly low, and it is for this reason that humid days cause us the greatest discomfort. In fact, we ordinarily experience discomfort on very humid days when the dry bulb temperature is well below 80 deg., a temperature which would be entirely comfortable if the corresponding relative humidity were sufficiently low.

The reason why the electric fan offers a measure of relief during summer weather is the fact that the evaporating effect of the air is a function of velocity as well as of temperature and humidity. Thus the draft from an electric fan increases the rate of evaporation and therefore cools the skin, affording the sensation of coolness, although the body temperature is only slightly, if at all, affected. Used unwisely, the electric fan is the source of much physical depression since a draft playing directly upon the unprotected skin of the arms and neck causes a local concentrated cooling effect by evaporation which is extremely difficult for the body to compensate. The electric fan should never be directed immediately upon the body, but so placed that the movement of air which affects the body is induced by the draft of the fan. The danger of this localized effect is entirely avoided in a building which is regulated by means of scientifically designed air-conditioning equipment since the air delivered is distributed through a carefully arranged duct system without drafts and with great uniformity.

It is entirely assumptive that in the very near future the production efficiency of the human being will be considered as carefully as that of the mere mechanical equipment, and that air conditioning will be employed as a practicable means of assuring maximum personal efficiency in any climate at any season under any inherent conditions within the plant itself.

New York City.

Electrification of Chemical And Allied Industries

Electrification of Industry Rapidly Increasing — Use of Motor Drive Is a Help to the Executive — Controllers for Motors Should Be Chosen With Special Reference to the Industry — Proper Use of Electric Drive

By C. B. Gibson
Manager, Metal Mining and Chemical Section, Westinghouse Electric & Manufacturing Co.

THE electrification of industrial plants has been a gradual process extending over the comparatively brief period of about 25 to 30 years. During the early part of this period the progress was naturally slower, but during the last 15 years the growth in the use of electricity in the various industries has been considerably more rapid. The original conception of the idea of employing motor drive arose from the necessity for a more convenient and flexible method of applying the driving force to machines.

Some of these machines were of a movable type with unusual motions and often located in some inaccessible place, which did not easily permit of driving by the methods in use then. The many advantages of this then novel method of drive were soon appreciated and motors for driving the more common machines, such as cranes, pumps, conveyors, etc., were soon adopted. A little later group drive and individual drive came into favor, until today electric drive is generally recognized as a necessity for economic and maximum production.

It is also recognized that the electrification of a plant or mill is not merely an engineering problem, comprising the generation and application of motors to machines, but it is one of the most direct, resourceful and accurate means for studying plant development. Unquestionably, electrification of industry has done more to aid executives in the study of plant problems than any other agency, because electrification is power scientifically applied and not merely an adjunct to a manufacturing process; and, further, because it is one of the important factors that lead to more efficient operation, better quality of product and general plant betterment.

Electrification in Chemical Plants

In the chemical and allied industries electrification is probably employed as extensively as in any other industry. As many of the branches of the chemical industry are users of large blocks of power in electrolytic and electrometallurgical operations, it is only natural that electricity be used for the various motor drives in the handling and preparation of the raw and finished materials.

Some indications of the rapid strides in the electrification of the industry are evident from data compiled on this subject. Considering the chemical and allied industries for the year 1914, the percentage of electric horsepower to total power, primary and purchased, was approximately 42 per cent. In 1919 it was approximately 56 per cent and it is estimated that this will reach approximately 70 per cent in 1924. These figures indicate the increasing rate at which electric drive is being adopted. In this connection it is interesting to refer briefly to the government census of manufacturers for 1919. For the fourteen major industries listed, representing the reports of 237,855 industrial establishments, the aggregate primary horsepower is 29,507,717. The number of electric motors installed is 1,483,039, aggregating 16,317,373 hp. This latter figure is made up of 9,347,556 hp. for rented, and 6,969,817 hp. for current generated in the establishment. The 1914 figures compared with 1919 indicate a gradual increase over this period.

While the figures for the strictly chemical and allied industries are relatively a small amount of the total, aggregating 2,043,525 of primary horsepower, they show the extent to which motor drive has been adopted by the industries in this country. The industries provide the major load of the central stations mostly in the form of motor drive, and it is gratifying to note that the central stations fully appreciate this. There is a co-operation and co-ordination of effort which is bound to reflect in a better understanding between the central station and the user.

Advantages of Motor Drive

The main advantages of motor drive are: Lower power costs, increased production, generally improved plant and working conditions and that the greatest return is realized when the entire plant is electrified. The larger the amount of power used, naturally the less the cost per kilowatt unit of energy, due to using greater amounts of power and on account of the diversity factor which means a more even and uniform load condition. Electric drive and automatic motor controllers reduce the amount of skilled labor very materially, as the automatic control device makes possible many self-controlled operations of the motors. Aside from these major reasons, electric drive helps in making a plant a model one in every respect, and this is an important consideration in this day when so much is being done for the welfare of workers. Other advantages are cleanliness, the absence of noise, and the suitability of the electric motor for most drives. Belts and line shafts are eliminated. One of the most important considerations is the ability of an electric motor to maintain the proper machine speed under varying and heavy loads, which in the final analysis means increased production.

Electricity is inherently more economical than steam in the great majority of applications, on account of its high electrical efficiency, low maintenance expenses of equipment, convenience and operating simplicity. Fundamentally, electrification offers one of the best opportunities to develop improvements. It provides an accurate means for determining all phases of plant problems, such as the power required by each machine or in each process. In the chemical industries many processes require extreme and accurate control in various stages of the process, and this is possible with electric drive.

Electrification Helps the Executive

The executive is concerned, among many other things, in reducing costs, increasing output and bringing up profits; and electric drive undoubtedly offers one of the greatest opportunities of accomplishing these ends. To

determine the economies affected through electrification, full consideration should be given of all the factors that may effect the results. Every factor entering into the problem should be considered, and the cost of power is only one of these factors. It is, however, the one common factor in every manufacturing industry, and by reducing the power costs, you can effect savings all along the line.

Practically all the industries welcome the opportunity to purchase power even where conditions might appear favorable for economic generation by the individual plant, because of the greater reliability of central station power and because the average executive feels he can realize greater returns by investing the capital in the business rather than in the power plant. The central stations also have made extensive studies of the requirements of motor drive for the various industries in order to have a better understanding of their problems and to stimulate a more active interest in the future extension of electric power in industry.

Choice of Cycle in a.c. Drive

As to the choice of sixty- or twenty-five-cycle power this is often determined by other conditions or processes in the plant. In several of the large electrochemical districts twenty-five-cycle only is available; and it is only natural that this same frequency be used throughout the plant—for the various motor drives, the haulage locomotives, industrial heating, lighting, etc. Outside of these few districts, sixty-cycle power is the predominating one. The sixty-cycle motors, except in very large sizes and slow speeds, are less expensive than twenty-five-cycle motors, and they offer a much wider range of speeds within certain limits. Alternating current squirrel-cage, wound rotor and synchronous motors are almost universally used, depending upon the type and character of the machine to be driven and the load conditions. Complete lines of these various motors in all standard ratings and speeds and for both twenty-five- and sixty-cycle are available from the electrical manufacturers. A few devices require direct current motors, such as on cranes or where a wide variation in speed is desired. Where relatively only few d.c. motors are used, it is customary to use motor generators for converting alternating into direct current for such purposes. If, however, large blocks for d.c. power are required, as in electrolytic processes, rotary converters are almost universally used on account of their superior operating characteristics, higher efficiency, wide voltage range, compactness and dependability.

Motor Drives in Chemical Plants

In the majority of motor drives in chemically controlled industries, squirrel-cage induction motors are used. They lend themselves particularly to this work on account of the absence of any sliding or movable contacts. This is particularly important where there are explosive fumes or materials present. Some of the applications in which motors are used are for driving conveyors, grinders, mixers, pumps, autoclaves, centrifugals, ball mills, kilns, etc.

While the large majority of drives are satisfactorily handled by squirrel-cage motors, occasionally the starting conditions are such that a motor which gives a higher starting torque must be used. For such cases the wound rotor motor, with reversing controller and resistance for speed adjustments, is most suitable. Again, some drives require mill type motors on account of the severity of the service. For driving centrifugal pumps or compressors, the synchronous motor is often used, and it offers a fruitful field for reduction in power costs. One of the inherent characteristics in the synchronous motor is its ability to improve the power factor of the system to which it is connected. As most central station rates are based on power factor, any improvement in the power factor often reacts in favor of the user.

Electrical Requirements of Chemical Industry Severe

In many respects the service demanded of electrical equipment by the chemical and allied industries is more severe than in any other industry. Here we have the deteriorating effects of acid and alkaline fumes, coal, coke, abrasive dusts, smoke, steam, splashing of liquors, etc. In order to render the electrical equipment impervious to these destructive agencies, especially impregnated coils and windings must be furnished. In this connection it is interesting to note that motors are obtainable with these special impregnating treatments from the motor manufacturers. In a few cases the conditions are so severe that, in addition to these special treatments, totally inclosed or ventilated motors are used as an added precaution. The totally inclosed motor is not obtainable in sizes much above 25 hp. on account of its inability to dissipate the heat developed.

In the larger sizes, ventilated motors are sometimes used. In this type of motor the end brackets are provided with openings. Clean, pure air is piped from the outside to the intake of the motor and the air is exhausted directly into the room. When the run of intake pipe is considerable and the speed of the motor is below approximately 720 r.p.m., the fan blades on the rotor will not provide sufficient circulation of air. If this is the case, or where several motors are to be supplied with air, artificial circulation is resorted to; and a small motor-driven blower is placed in the supply pipe feeding the various motors. For several reasons many users favor the positive method of air circulation for all ventilated motors. In supplying air to ventilated motors, care must be exercised to see that the air is not contaminated with fumes or foreign materials. For some applications a motor with drip-proof covers is sufficient. In this type the end brackets are provided with vanes which divert any foreign materials or drippings of liquor from the motor.

Motor Controllers

The control equipment employed for chemical plants is equally as important as the motors. There is always a type of control which is best suited and adapted to a particular type of motor. Experience indicates that a full knowledge of the motor characteristics and its performance is necessary in order to properly apply the control. Starters remotely controlled by means of a push button or small master switch are absolutely necessary for certain applications, especially when the motor is in some inaccessible place or where a life hazard is involved, such as in explosive plants. If explosive conditions exist, the completely immersed starter is generally used. In other types of starters where fume conditions are bad, special attention must be given to the contracts, flexible shunts, etc., by treating them with acid- and moisture-resisting materials. It can be con-

servatively stated that the executive or plant engineer in considering the electric drive can be assured of obtaining properly designed apparatus for all the applications.

While chemistry guides the manufacturing processes of the chemically controlled industries, the electric power is performing its duty silently and efficiently, resulting in increased production, more uniform product, and at minimum power requirements. There are several different types of drive either group or individual, belted or direct connected, etc. The application of these different types is pretty well determined, and is according to a well defined policy of broad plant development, including plans for future growth.

Electrification of Existing Drives

In the past but little attention has been given by executives to the rehabilitation of old plants, usually with steam engine drive; but this condition has rapidly changed and many of these plants have been electrified —using central station power, as it is then unnecessary to invest in a power plant, and the first cost of this change over is a small amount compared with the savings effected therefrom.

Other Possibilities of Electrification

Aside from the motor-driven machines in the chemical and allied industries, large blocks of power are used in electrolytic and electrometallurgical operations. It is not the intention to discuss the use of electricity in these processes, as they usually involve processes which could not be economically employed by using any other source of heat. In passing, brief mention should be made, however, of the possibilities and future of electrical heating in many of the processes. The growth in the use of electricity as a heating agency has been phenomenal. Many executives and others unfamiliar with the possible economies of electrical heating casually dismiss it from their serious consideration, on account of feeling that it is an expensive and impractical method. Fundamentally, there are many reasons why electric heat is superior to any other heat, and these reasons should receive earnest consideration. Some of these reasons are as follows:

(1) Electricity, regardless of the form in which it is used, may be applied at the desired place and in a definite quantity.

(2) The heat may be absolutely controlled.

(3) The central station power is available for heating 24 hours per day.

Applications of Electric Heat

A few of the possible applications in the chemical and allied industries for electric heat are: Heating kettles, vacuum chambers, evaporators, autoclaves, stills, vulcanizers and heating, drying and enameling ovens. The greatest advantages from industrial heating are obtained when the heating process is worked out in connection with other operations and processes. In laying out a plant for motor drive the process can often be improved or the time shortened if the heating processes are considered at the same time. A true estimate of the economies possible can be determined only from a consideration of all the factors entering therein.

The effective utilization and application of electrical power demands the broadest and widest experience and intimate contact with the industry. The executive is interested in knowing the most modern, efficient and economical method for applying power. In considering the electrification of a steam plant, he must know the maintenance cost of the entire steam plant from the coal pile to the crank pin, and balance this against the maintenance of the electric drive; and it will be found that the cost of power is the one common cost in every operation. In considering a new plant, he must consider the most economical processes and methods of handling of materials through the use of electricity; and, in the final analysis, a true valuation of these economies will undoubtedly point the way to worth-while savings through electrification.

East Pittsburgh, Pa.

Disadvantage of Low Power Factor

In a recent issue of *Industrial Management*, George E. MacLean, electrical engineer, of Sherbrooke, Canada, points out the disadvantages of low power factor. As this subject is of particular interest now when so many chemical engineers are considering the electrification of the drives in the plants under their charge, it is worth while to quote, in part, Mr. MacLean's article.

Power Factor Explained

Power factor is explained by Mr. MacLean as follows: "We contract for water at 120-lb. pressure and by some means or other send a back pressure of 10 lb., hence the water will have to be sent out at 130-lb. pressure to allow us to receive 120-lb. pressure, and we will have to pay for this extra 10-lb. pressure."

Similarly, in applications of motor drive, we have a back pressure called reactance—due to induction—caused by running many small induction motors and underloaded large motors. To overcome this reactance there must be supplied an excess of energy over that which goes into useful work. Power factor is the ratio of the useful electrical energy supplied to the total supplied and is expressed in per cent. Hence 85 per cent p.f. means that 15 per cent of the energy supplied is wasted in heating the electrical equipment, and only 85 per cent is available for useful work.

Disadvantages

"Excess heating causes a premature deterioration of insulation, which causes breakdowns and burn-outs of induction motors.

"Low power factor causes another condition with induction motors that does not show itself, as it affects the power consumption and can only be determined by making tests to find out the increase of this magnetizing current.

"Low power factor causes poor line regulation, which in turn decreases the torque of induction motors and increases the magnetizing current. This increase of magnetizing current is an added load on the system and has to be paid for at the same rate as though it was useful.

"For one who is not familiar with electrical terms and trigonometry most of the explanations of power factor are difficult to understand.

"We will say as an illustration that we contract for power at 85 per cent p.f. but can keep the power factor of our plant at only 75, and we consume 10,000 kw.-hr. at 6 mils. Our power bill equals 85/75 of 10,000 times 6 mils, or $67 instead of $60, or 11 per cent of the power bill is paid out for this wattless current."

Increased Production Efficiency in the Industries

Concise Statements by Leading Representatives of the Chemical and Related Industries in Answer to the Question, "What Would Contribute Most to Increased Production Efficiency in Your Industry?"

[N THE following pages the reader will find a group of frank statements by leading industrial representatives. They lay bare outstanding deficiencies in roduction processes, which, if remedied, will place hose industries on a more efficient production basis. lext in importance to maintaining an industry in a tate of general health is the frank recognition of weak pots that need improvement, and a vision of possible emedies. In fact, an industry cannot rightly claim to e in a healthy state unless it exhibits that forward-ooking spirit that seeks constantly to increase its efficiency in the interest of better service to its clientèle.

Judged by this standard, the chemical and related ndustries served by *Chem. & Met.* can lay claim to an xceptional degree of vigor and vitality. Certainly it an be said of the least progressive that it has within s ranks one or more men of vision who see clearly hat needs to be done in the interest of more efficient roduction. Their opinions will repay many fold the alue of the few minutes required for their reading.

A Neglected Ingredient in Acid Manufacture

By Fred C. Zeisberg
Chemical Department, E. I. du Pont de Nemours & Co.

THE chemistry of most of the acid processes in use today has been thoroughly worked out, hence it is eedless to look to any great increase in the chemical fficiency of these processes through further laboratory ork. How, then, can our acid industry be made more fficient without going to entirely new processes?

Before this can be answered with exactness for any ndividual process it can be safely asserted as a general ruism that improvement can be achieved only to the xtent that an exact knowledge is possessed of the mounts of ingredients required to make a unit quanity of the finished product. In other words, it is ecessary to have firmly established a thorough system f chemical control of processes and chemical accountng of the ingredients in process.

But this is not all. The amount of labor necessary, nd its grade; the amount of repair labor, when this s a separate item; the amount of repair material; and ast but not least, the power—all these items must be nown accurately.

There are many plants where none of these items is nown, except in a general way. There are more where he raw materials alone are known. There are a few here all of the items except power are known. And here are practically none where it can be stated, with ny assurance, that so and so many kilowatt-hours and o and so many pounds of steam were used per ton of nished product.

This is a strange state of affairs. In many processes ower is one of the most expensive raw materials, yet s shamefully wasted, probably because the coal used o generate it burns up out of sight in the power house and its converted energy flows unostentatiously into the plant through wires and pipes. If these wires and pipes were equipped with meters, so that waste of power and wrongful use of power could be checked up, it is safe to assert that 50 per cent of the power used in the acid industry in this country today could be saved.

In each dwelling house in the larger cities there are generally installed three meters—a water meter, a gas meter and an electric meter. If the public service corporations consider it profitable to install these in order to prevent willful waste of power and to make a proper distribution of the power costs, why would it not be equally profitable to install them in the various houses on a large plant, each of which uses many times the power of the largest dwelling house? Why not, indeed?

Wilmington, Del.

The Fine Chemical Industry Is Dependent on Pride and Loyalty of the American Chemist

By Carl Pfanstiehl
President, Special Chemicals Co.

IN THE production of rare and fine chemicals we encounter a new production problem foreign to the manufacturing methods characteristic of America. We are not engaged in moving tons of material, and therefore must shift our interest from that of engineering to the personal element. Germany's monopoly of the fine chemical business in the past was due largely to the fact that she had available a large body of highly trained men of Ph.D. quality, working individually to produce the unusual commodity. Due to the system under which these men worked, their services were obtained at a very low cost.

If we are to make a success of this branch of the chemical industry in America, we must develop a plan whereby the interest of highly trained men can be obtained at a profit to themselves and at a cost which will enable their products to compete with the foreign goods. There seem to be possibilities in the example of a number of young Ph.D. candidates who are making a few rare chemicals "on the side," thus assisting themselves financially and at the same time producing chemicals of value in their particular studies. Another point of equal importance is that in America we have to devise ingenious means of doing work with less labor than heretofore in order to survive. This stimulates the genius of chemists in our industry to devise methods improving on ordinary procedure and substituting automatic control, for example, to decrease the costly element of personal supervision.

In the plant, or more properly the laboratory, appeal must be made to the pride and personal interest of the man who makes the products. It is not possible to institute a discipline comparable to that of large-scale production where tons are handled on a daily schedule.

And although the problems of system and record are the chief difficulties with such chemists—for these men are largely of the research type—the solution of production problems lies in appealing to their pride. The man making fine chemicals cannot be treated as a cog in a machine. His efficiency depends on his skill and knowledge and above all on his interest. This is another argument in favor of the movement now on foot to raise the standing of the chemical profession in the eyes of the public and place it on a level with the medical, legal and other recognized professions.

The chemist must be given this sense of dignity. The intelligent production system must take into account the importance of his pride and interest and give him an opportunity in some way to participate in the profits of his work.

The fine chemical industry is extremely important to problems of American defense, industrial development and public health. It is hard pressed just now and therefore is the most interesting to American chemists and worthy of their loyalty and support.

Highland Park, Ill.

Lost Motion in Explosive Making Due to Needless Variety of Products

By G. M. Norman
Technical Director Hercules Powder Co.

THE explosive industry may be divided into three main divisions:

I. Black blasting and black sporting powders.
II. High explosives, usually containing nitroglycerin.
III. Smokeless powders (propellant).

The types of black blasting powder made do not, as a general rule, exceed ten or twelve. The machinery used is rather simple compared to that needed in the manufacture of the two other classes, while only three or four ingredients are required. In our opinion, the manufacture is so well developed at the present time that few improvements may be looked for in the future.

High explosives, comprising dynamite, blasting gelatin, etc., is the largest peace-time branch of the explosive business, judged by the capital invested and the value of the production.

Because of high transportation costs, it has been found advisable to locate explosive plants near the point of consumption. This has resulted in the construction of a large number of factories the aggregate capacity of which is in excess of the present demands or needs of the country. Because of the nature of the materials handled, the industry has not been able to use to the same extent all the various mechanical and labor-saving devices that are common in other manufacturing operations; however, the explosive industry has invented and uses numerous mechanical devices intended to save labor and to reduce the hazard always present in explosive manufacture. In this respect the industry in the United States is far in advance of our friends across the sea; it is only fair to say, however, that the explosive makers of Europe are not permitted by their various governments to introduce mechanical devices, however much they may desire to do so. Hence we think there is little room for major improvements or changes in the mechanical equipment of the industry when producing the present type explosives.

Practically all explosive plants in this country are managed by staffs of technically trained chemists and engineers. The plant efficiencies are high in practically all chemical operations and there does not appear to be very much opportunity to improve upon the results now being obtained.

In the matter of accounting, the principal companies in the explosive industry in this country have a highly developed system of cost accounting, which enables them to determine costs with accuracy.

The one thing we think that would help the efficiency of the explosive industry in the United States today is the standardization of the product. There is nothing new or novel in this statement, and several attempts have been started in the past to bring about a reduction in the almost numberless grades, sizes, styles, etc., in which explosives are placed on the market. The fact is, however, that today there is a greater variety of explosives offered to the trade than is needed or necessary. Who is responsible for this condition—the salesman or the customer—and how it can be remedied we are unable to say. We do know that the result is an increase in manufacturing costs because of a decrease in output of machines due to changing from one grade or size to another, an increase in the amount and kind of ingredients used at each plant, an increase in magazine stocks all over the country and an increase in cost accounting necessary, etc., all of which someone has to pay for.

We very much question if any practical user of explosives can tell any difference between a 17 per cent dynamite and a 20 per cent dynamite, or a 27 per cent dynamite and a 30 per cent dynamite in actual use. Furthermore, we find straight dynamite, ammonia dynamites, high-freezing and low-freezing dynamites, permissible dynamites—both high- and low-freezing—straight gelatin dynamites—high- and low-freezing—blasting gelatin, etc.

There are, of course, thousands of combinations possible under the above conditions. As a matter of fact, the number of different packages in a factory magazine will not usually exceed seventy-five or eighty. This number, however, is excessive, and in view of what has been done in other lines of manufacture to eliminate odd sizes, it would appear that not only an intelligent self-interest of the explosive manufacturers but ordinary economy on the part of the consumer demand that such reduction be made.

Wilmington, Del.

Innumerable Formulas of Fertilizers a Drawback to Production Efficiency

By F. S. Lodge
General Superintendent, Armour Fertilizer Works

FROM a strict manufacturing viewpoint the one outstanding cause of inefficiency in production in the fertilizer industry is the multiplicity of analyses that every factory is called upon to ship. It seems to be a common belief of scientific agricultural investigators that a properly selected offering of twenty different analyses should satisfy the agricultural needs of any one locality. These, with certain raw materials and bone meals, will satisfy any crop requirement in the territory served by any one factory, with the possible exception of special territories, such as Florida, with its varied fruit and truck crops. In contrast with this we find the average factory called upon to furnish in a single season at least one hundred different analyses of mixed goods, besides raw materials. Many of these

analyses vary by only a quarter or a half per cent in some one ingredient. Certainly our crops are not such fastidious feeders as to demand such slightly varying rations.

The factory, in order to be able to ship any analysis called for, must either carry stocks of individual tags and bags printed to suit each requirement or else be equipped with printing machines in numbers sufficient to print them at a moment's notice. Each extra brand requires that the chemist make out a new formula, that the factory clerk must set up a new set of records in his books and furnish the factory foreman with a new manufacturing order, that the accounting department and auditors have an additional item to carry all through their records.

The most noticeable loss, however, is in the factory, where each change in the analysis shipped by one of the mills requires that the machinery be stopped and cleaned, with consequent idleness of men and equipment. Ingredients and weights must be changed and the entire operation slowed up till familiarity with new figures becomes a routine again, for the intelligence of the average fertilizer laborer is limited and he does not readily adjust himself to varied conditions.

The secret of low cost in the fertilizer factory is maximum tonnage. Every time a mill is stopped to change the analysis being shipped, it results in a loss of approximately 2 per cent of its day's output. Ten changes a day are not uncommon, so that the manufacturing cost of goods shipped is increased 20 to 25 per cent.

This condition in the industry is brought about by the salesman selling anything the customer suggests he wants, rather than what he needs; to his practice of juggling the analysis a fraction of a per cent in the higher priced ingredients, in order to undersell a competitor, and to his offering to duplicate any goods offered by a competitor.

A secondary contributing factor of similar nature and producing the same effect is the non-uniformity of state laws, particularly as to branding of fertilizer packages. A bag of fertilizer branded according to law in one state would be barred from sale and could be confiscated in an adjoining state.

Proper adjustment along these lines will aid very materially in reducing operating costs and increasing operating efficiency.

Chicago, Ill.

Steady Production the Key to Efficient Production in Dye Manufacture

By George A. Prochazka, Jr.

QUESTION the dye manufacturer of today as to the condition of his business, and he will probably recall the latest developments on the embargo and the legislative situation and tune his answer accordingly. These are troublous times for the American dye manufacturer. Granted reasonable protection, it is not impossible for America to compete successfully against foreign dye manufacturers. But in order to do so, it is necessary to apply the same principles of good engineering practice and good business judgment that are essential to the success of any other enterprise.

There are no "secrets" in the dye business. There are a few "kinks" in operating practice which, in the hands of one manufacturer, may give him a temporary advantage over competitors, but eventually such information becomes common property, and he who survives competition will be he who maintains production efficiency by the application of technology and builds up his company by the application of sound business principles.

Production at Capacity Essential

The one outstanding factor in increasing production efficiency in the dye industry today is that of maintaining production at capacity. The dye business is decidedly seasonal. The demand for its products fluctuates in a manner which is sometimes most mysterious. A plant standing idle for a short time will eat up the profit of a much longer time of capacity production. When this fact is realized by the dye manufacturer he will devote his ingenuity to the establishment of a production schedule and a plant arrangement which will enable him to approach the goal of continuous capacity production.

The dye industry has been through boom times, just as many other industries have been, during the war and the post-war period. There are some lean years still to come. The effect of this general prosperity extended to the users of dye as well as to its manufacturers. Many of the consuming industries which sprang up during this period, when quality was a secondary consideration, are now face to face with the necessity for meeting the competition of superior products. Many of them do not know how to use dyes. The hundreds of specialized uses for dyes require a definite knowledge of the best dye for each individual purpose. While the dye manufacturer can co-operate to mutual advantage with the ultimate consumer, it is generally admitted that there is too great a distance between the dye manufacturer and the ultimate consumer. Co-operation would be much simpler if there were fewer middle men, and the manufacturer would be able to meet the individual demands of a customer to better advantage.

Research a Necessity

In an industry which is as fundamentally technical as is the dye business, a certain amount of research is a constant necessity. The value of a research organization, however, cannot be expressed in terms of the number of chemists employed, but must be recognized as directly proportional to the ability of the research staff. In other words, a real research chemist, with years of experience in research, can accomplish much more in a dye plant than a flock of chemists of less experience and ability. Not only in this respect is the personnel in a dye plant important. Eventually, the process is turned over to the operating crew. The ability of these men is analogous to that of a chef, who can concoct a delicious confection from the same recipe that will yield an unappetizing mess when prepared by an amateur. A case comes to mind where one operator had been conducting the same operation in a dye plant for 20 years. One day he died and, naturally enough, took his technique with him, and it was many months before that plant was able again to produce material which was up to specifications.

Cost Accounting of Great Importance

The subject of cost accounting is of the greatest importance in the dye industry, but here again the

extremely specialized nature of the business must be taken into account. The majority of dyes are produced in small batches. Small errors are apt to cause a heavy expense to be laid to some particular product. The production of the various units in the plant fluctuates with the demand. The material accounting must be in an extremely high state of development. The successful cost-accounting system for the dye manufacturer is the happy medium between an elaborate accounting staff, involving considerable overhead expense, and the old-fashioned method of judging the production cost by the aid of that second nature which is acquired by long experience. The common-sense attitude on cost accounting is that any system is worth just about what it saves the company which uses it.

Newark, N. J.

Fundamental Research in Cellulose Industries Must Keep Pace With Commercial Development

By W. O. Mitscherling
Wilmington Experimental Laboratory, Atlas Powder Co.

WHILE the cellulose industry of this country has reached high production efficiency in regard to automatic equipment, improved cost accounting and standardization of operating procedure, little advance has been made in the research of cellulose itself. It is this which would contribute most to increase production efficiency. Our commercial future and welfare depend to some extent upon the cellulose industry.

America is the cotton king; a great deal of wealth of foreign countries depends on our cotton cellulose. While the cotton from Egypt is of very excellent quality, the amount available is limited. This is especially true for cotton to be used as a raw material for cellulose compounds. America also has a great supply of woods of all kinds, sufficient raw cellulose to supply all demands for generations to come. And yet this tremendous industry uses a material the conventional standards of which are defective in every respect.

A bibliographic essay of investigational work on the compound cellulose, either cotton or wood pulp, shows that we have to deal with a highly complex substance whose chemical constitution has not been, as yet, fully determined. The splendid researches of our American scientists and the work of the Forest Products Laboratory give us valuable information about the compound cellulose. While we know the compounds derived from cellulose, we have no light on the manner in which cellulose itself is synthesized.

Thousands of men and women are employed in the cellulose ester industry. The paper and textile industry give occupation to additional thousands of skilled and unskilled workers. A goodly part of the chemical industry is devoted to the manufacture of materials used by the cellulose industry. Manufacturing methods have reached a high state of development, and yet we can scarcely say that our analytical methods for determining the purity of cellulose are exact. It will take time and the co-operation of universities and industrial institutions to work out these methods and to adopt standards.

Let us ask our universities to help us in this work. It is not a question of developing manufacturing processes, it is merely a question of helping the industrial worker to adopt exact methods and standards. To do this the industries must help, not only with suggestions but also financially.

Since the benefit of such co-operation is extended not only to the paper and pulp, the chemical cellulose and the textile industries, but also to the entire chemical industry, there is reason for very general interest in cellulose research.

This would mean increased production efficiency and economy, increased demand for chemists and increased wealth to our country.

Wilmington, Del.

Ceramic Manufacturing Needs More Intelligent Technical Control

By Ross C. Purdy
General Secretary, American Ceramic Society

INCREASED production efficiency calls for more ware per hour without reduction in quality or wage. The high wages paid in this country have brought the requirement for more highly productive methods and equipment, which, in turn, has brought the requirement for more positive control methods and records.

Not altogether as a consequence, but paralleling these changes, acting on and reacting with the operating developments, there has been a decrease in number of small plants with their old-fashioned methods and an increase in number of large plants with modern methods. There are 5,000 fewer brickyards in this country today than there were 20 years ago and yet the production of bricks has increased many fold.

The big building enterprises require large building material producing plants. Chain restaurants, hotels and stores call for large producing potteries to fill their current orders. These are some of the present influences that did not exist a few years back.

These are the days of large production per unit labor time of the individual workman in ceramic plants as it is in all other sorts of manufacturing; and there is in the ceramic plants that same increasing need of accurate operating control and better methods and equipment as in any manufacturing.

While there is the increasing necessity for production efficiency, there is also an increasing demand for better quality. This calls for better selection and preparation of the raw materials. Here again follows the need for better control methods.

Standardization and specifications of materials and products are not fads; they are economic necessities. Elimination of shapes and sizes is not a fad; it is an economic necessity. Cost records and their analysis are not fads; they are economic necessities.

In the manufacture of some ceramic wares they are finding some of the machine processes inadequate from the viewpoint of both cost and quality. There is today more casting of large wares, complicated shapes and even of some of the simple shapes. Just as the foundryman has learned the economies of jogging, of stacking and of gang molds, so have clayworkers. The glass manufacturer today is more dependent on automatic machines because of the necessity to increase production per labor hour, and to meet the more strict specifications of product.

New designs of kilns, driers and handling devices together with closer inspection of materials and products, are the economic requirements of the present day. The processes and equipment that effect economies in one ceramic line will not always effect them in others. Car tunnel continuous kilns have produced economies and higher quality of ware in some ceramic lines, while

in others the cost records show in favor of the periodic kilns. Under some conditions gas producers are economical, while under others they fail to show economies of any sort. But there is no kiln, process or equipment which cannot be made to produce more efficiently by subjecting its operation to close control observation. The recent demonstration by the Bureau of Mines on a variety of brickyards of the possibility of from 15 to 30 per cent saving in fuel, quicker turnover of kiln without a change in kiln, fuel or labor and with more positive control of quality and a reduction in amount of "seconds" bespeaks the economic importance of technical control in manufacturing of even so crude a ware as common bricks.

Increased production efficiency today will follow from the more searching technical and scientific investigations which the manufacturers are supporting both in groups through trade associations and singly. The consequence of these investigations will be closer and more intelligent technical control. This is the greatest need in ceramic manufacturing today.

Columbus, Ohio.

Standardization of Product and Process Needed in Pulp and Paper Industry

THE greatest present needs of the pulp and paper industry to insure increased output consistent with quality and decreased costs are the establishing of standards at commencement and throughout the stages of manufacture and such technical control through men and instruments as will maintain conditions commercially close to established standards.

Our raw material is handled in such quantity and from so many sources that any inspection and sorting much better than at present would be prohibitive in cost, so that an established standard should be such as can be reached easily and maintained through mixing and averaging lots of material received. After receipt and before going into process much good work can be done along the line of improved storage of wood, uniform moistening, rotation of piles, etc.

While in one sense not a raw material, the water supply certainly enters into the process very vitally. Equipment in settling basins, filters, chemical treatment should be ample enough to insure substantially uniform water throughout the year. Even temperature can be kept approximately uniform through use of heat interchangers, condensing water, etc.

Throughout the process the strictly chemical ends, such as preparation of liquor, bleach, etc., are pretty well measured and controlled, but the physical end as exemplified in mechanical handling and measuring of semi-colloidal stock offers a large field for effort. The work of both chemists and technical mechanics should be directed toward uniform material delivered to machines. In the case of somewhat parallel processes where raw stock is necessarily variable, very definite schemes of mixing and averaging have been adopted. The pulp mills can improve materially along this line.

Initially the chip house can be made a much more exact process, chipper and chipping put nearer on a par with planing mill practice, and screening and sizing chips can be done much more carefully, each size later being given its proper controlled cooking time.

Digesting apparently must be a batch process for some time. It is therefore all the more important that large storage capacity be provided after the digesters, so that the inequality in the various cooks be ironed out and stock going to the drainers, bleachers, etc., be average of many cooks.

Bleaching is pretty well controlled technically, although a decided weakness exists in the means of maintaining stock consistency. Devices are badly needed that will be simple and substantial, that will indicate not only stock consistencies but freedom of the stock.

Proper beating is at present far too much a matter of opinion. With proper instruments showing power input, weighting of roll, coupled with standard inspection of the condition of beater and Jordan knives, the stock to the machine chests could be delivered in a vastly more uniform condition than at present.

At the machine we need close control of room humidity and temperature, uniform speed calling for removal of vapor, drainage of driers, close speed regulation and uniform steam pressure.

In the finishing room and coating mills there is not so much room for improvement, though better humidity control when drying would make for better paper grades.

Freedom from fire in paper mills and other manufactures is largely a matter of inspection and installation of protective devices. Why will not similar anticipation of trouble in the process through technical inspection and follow-up of machinery result in equally large dividends?

The technical personnel end is perhaps the most difficult problem to solve. We have seen in the last decade the establishment of chemists as a necessity to paper making. The introduction of technical mechanics may not follow the same methods. The latter must be brought in through establishing prescribed courses leading to a fairly definite executive job about as the large electrical companies maintain their technical forces.

Sound Advice for the Petroleum Refiner

By T. G. Delbridge
Chief Chemist, The Atlantic Refining Co.

IN reviewing the problem of increasing the efficiency of petroleum refining, there appear to be three factors that warrant the careful consideration of every petroleum refiner:

(1) Utilization of experimental data now available.
(2) Further scientific study of process problems.
(3) Judicious selection of products to be manufactured.

While the scientist is rapidly becoming more indispensable to a modern refiner, there is still, in some quarters at least, a mild antagonism toward the college-trained man. His results, conclusions and recommendations are sometimes looked upon with doubt and suspicion. A perfectly practical and financially attractive process may lie dormant in laboratory files for months before being taken up. In general, the solution of any problem represents only half the necessary work, the other half being to sell the idea to the management. It is proper and necessary that every new project be carefully scrutinized. Such scrutiny, however, should be prompt and decisive. Delay is not only expensive when good ideas are neglected but is extremely discouraging to the scientific staff. It is suggested, therefore, that the first step in increased efficiency is prompt utilization of all scientific information available either from private or public sources.

The second item in the list needs but little comment.

While refining operations will probably always require the exercise of some personal judgment, it is highly desirable that this be reduced to a minimum by controlling conditions in such a manner that the desired result follows not once but always. This requires careful and thorough scientific study. The greatest foe to progress has been impatience and guessing. Obviously, scientific information can be obtained only with a competent staff large enough to cope promptly with the more important problems and so co-ordinated within itself as to function smoothly with the operating organization. Such a scientific staff will quite naturally furnish about half the operating executives of the future, and at least some of its men should be selected with that objective in view.

The third suggestion is a plea for more care in deciding what products should be made. Granting that the customer is always right and that he must always get what he wants, nevertheless it is frequently necessary to assist him in determining what he wants. The present age is one of specifications and there is a real tendency to overdo in this respect. The pendulum is swinging from the position where the customer took what he could get to that where the customer will tell the refiner what to make. While there can be no criticism of a rational specification, even for petroleum products, there are many instances where the refiner bears an excessively high cost to produce a product of inferior value to the user. There is a grave danger along this line. Highly refined products are not always desirable. For certain purposes they may easily be over-refined. The interests of both user and refiner are identical so far as petroleum products are concerned—namely, the most satisfactory material for each purpose in quantity to meet but not over-supply the demand.

Philadelphia, Pa.

Research on Design, Quality and Uniformity Essential to the Rubber Industry

By W. C. Geer
Vice-President in Charge of Development, The B. F. Goodrich Co.

THE rubber industry is distinct from the pure chemical industries, in that the majority of articles made, particularly tires of various kinds, undergo service of a character which wears them out. There is a life or endurance factor, whereas in chemicals the substances made usually must withstand a composition requirement only. In rubber goods, therefore, there is ever in front of the production engineer the question of design, which must be maintained so that each of the numerous units may render to the consumer the full measure of service.

A major problem of production efficiency is so to produce the millions of tires, heels and shoes, the miles of hose and wire in a way to maintain in each of them an endurance quality. It is probable, when one considers the tire production of over 35,000,000, a boot and shoe production of over 160,000,000 and the many millions of feet and numbers of units of the various other articles, that there today exist differences in quality.

The rubber industry today is well manned, the skill of its workers and their selection and training are high. But the production efficiency engineer should for some time bend his energies toward harmonizing labor and processes that each unit may equal in service value each other unit. This, in my judgment, is the next most essential step before the maximum achievement of production will be obtained.

Co-ordinated with greater uniformity of production lies the field of more fundamental research. Much has been accomplished, particularly during the past 5 years, along special lines, which, however, have had to do with improvement in the details of methods of manufacture of articles now known. Accelerator work and reclaiming of old vulcanized rubber are the two greatest advances made since the discovery of the fundamental one of vulcanization, but methods of mixing and methods of handling unvulcanized rubber are still much as they were 70 years ago.

Research to give greater adaptability of rubber compounds to broader uses and thus to give to the consuming public the advantages which rubber, of all substances, possesses is still another field. We know that the quantity of crude rubber to be derived from plantations is practically unlimited. Therefore the manufacture of numerous products not now made of rubber, by methods so economical as to permit of the extended use of such new products, is a field of investigation vast enough to occupy the attention of the best construction and production engineers in the industry.

Akron, Ohio.

Need of Research in the Portland Cement Industry*

By P. H. Bates
Chief, Division of Ceramics, U. S. Bureau of Standards

NOTHING has served to demonstrate to the portland cement industry the possibilities of increased production efficiency more than the results which have been obtained by the installation of properly designed waste-heat boilers and the power plant equipment required by such installation. Though it is true that some of the first to attempt the use of such waste-saving devices met with dismal failure, yet those who continued development along these lines, or the others who studied the first failures, have met with such success that now all concede the marked increase in plant efficiency obtained by the use of the waste heat recovered from the rotary kiln. If a plant with but three 150-ft. kilns can generate from the heat formerly wasted by these not only enough power to run the entire plant but sell an unrequired surplus, what more striking example of the possibilities in production efficiency could be desired?

What Is the Most Efficient Length of Kiln?

Such results have been obtained by the first intensive study of but one feature of plant equipment. There is reason to believe that the study of all the other features might produce as highly gratifying developments. Hence why not continue the study with the kiln and determine the most efficient length of kiln for any type of raw material and the proper ratio between length and diameter? Kilns now vary from 6 to 12 ft. in diameter, and from 60 to 240 ft. in length.

The settling, for the time being, of the fineness requirements in the standard specifications for cement is too recent to have dropped from the memory of many. The discussion of this will be recalled to have hinged upon the ability of certain of the common types of grinding mills to produce the fineness of product asked for by many and upon the cost of such extra grinding by any type of mill. It served to bring out strikingly the fact that the type of mill used was largely a matter of personal preference, without any basis of actual data

*Published by permission of the Director of the Bureau of Standards of the U. S. Department of Commerce.

of the efficiency of the various types used. Here again the question is not one of variety alone but also of size. What should be the ratio of length to diameter of tube mills, or what should be the diameter of the various types of ring mills for the greatest efficiency?

Research the Important Factor

There can be no doubt that the most important factor toward increasing production efficiency in the portland cement industry would be research, especially along the lines of operation of the mechanical plant and leading toward the standardization of plant equipment. This is suggested without even considering the need of research along chemical lines such as might lead to certain changes in composition or raw material as would reduce the clinkering temperature or the need for the usual degree of fineness of the raw material. It is suggested also without regard to the desirability of research to determine whether portland cement as now made is of the proper composition for all purposes, or without regard to investigations which might lead toward such radical changes in production procedure as recently brought forward in France with the appearance of the "fused cements."

Mechanical research is the feature which can bring in the shortest time to this huge chemical industry—the manufacture of portland cement—the greatest increase in production efficiency. While it is to the credit of the chemists and chemical engineers that this industry has grown from nothing to a value of annual production of close to $225,000,000 in somewhat less than half a century, yet for this industry to gain the efficiency of production that will be demanded of it to bring it to the level of the other chemical industries, it will be necessary for the chemists and chemical engineers to see that research is directed along these lines.

Washington, D. C.

More Engineering Research and Standardized Raw Materials Needed by Paint and Varnish Industry

By C. D. Holley
The Sherwin Williams Co.

SIXTEEN years of practical experience in the manufacture of paints and varnishes has convinced the writer that standardization of raw materials is by far the most important step to be taken in obtaining increased production efficiency in this industry. Except in a few instances it has been a matter of extreme difficulty to purchase these raw materials on a fair specification basis. Possibly this is due to the fact that very few paint and varnish companies have attempted to buy on specifications and the various sources of supply have therefore not felt the need of standardizing their products or giving to those companies which endeavor to purchase according to specification the consideration to which they are entitled.

Many of the larger paint companies attempt to run on established production schedules, and unless their incoming stocks of raw materials are uniform in quality, the rate and, therefore, the cost of production are interfered with—often quite seriously. This is particularly true on account of the fact that most paint factories use a minimum of skilled labor.

It is the writer's belief that other features which work toward increased efficiency, such as automatic process control, improved machinery and facilities for handling and conveying raw materials, efficient training of workmen, are of secondary importance as compared with the problem of obtaining uniform raw materials. This is largely because of the fact that these materials constitute a large portion of the cost of the paint or varnish in question.

Fundamental research should not be neglected, and particular attention should be directed toward a better understanding of the underlying principles of paint grinding. The necessity of this is shown by the fact that there is today no standard or generally accepted type of dressings for paint mills. Probably no other industry knows less about the possibilities of its equipment than does the paint grinder. Perhaps this is not to be wondered at, as the paint and varnish industry has until very recently given but little thought to engineering research.

Fundamental Research on Purification Methods the Greatest Need in the Beet Sugar Industry

By H. W. Dahlberg
Research Manager, The Great Western Sugar Co.

THE beet sugar industry is in one way fortunate in having only one main product—white granulated sugar. The quality of this product is all that can be desired, it being of a very high degree of purity. The greatest possible advance in the industry during future years will therefore doubtless be along the lines of increased quantity per dollar expended, rather than in improved quality.

I believe the greatest need of the industry today is more fundamental research, particularly in several of the most important steps in the process of extracting and refining sugar from beets. The lines of research which look most promising to me from the practical "dollars and cents" standpoint are the following:

1. The production of beets of high sugar content and minimum amount of soluble impurities.
2. The elimination of impurities in the refining process.

The quality of sugar beets varies greatly with soil and climatic conditions. While climatic conditions are beyond our control, we do have some control over soil and irrigation. It has been well demonstrated that beets which are grown in heavily manured soil, or soil very rich in soluble salts, are relatively low in sugar content and of a low purity. The same is true of beets which have not been carefully thinned and cultivated, or have been watered excessively with irrigation water containing mineral salts. In order to obtain beets of high quality it is necessary to start with carefully selected seed into which the desired attributes have been bred through many generations, and follow up with scientific soil treatment. In a period of 30 years preceding the war several of the European countries, by systematic seed breeding and selection and studies in fertilizer control, were able to reduce the mineral salts in beets by 30 per cent and increase the sugar content very materially. While our naturally rich soils do not respond so readily to fertilizer control as do some of the European soils, I believe research work conducted from both the botanical and chemical standpoint will yield large returns in securing beets of maximum sugar percentage and purity.

The principal purification of juices from sugar beets is done by treatment with lime and carbon dioxide. By

this treatment about 25 per cent of the impurities present in the juice are eliminated, the remainder causing a loss of sugar in the form of molasses, from which sugar cannot be extracted except by special processes. This purification step is by far the most important in the entire refining process, and it is rather surprising that no essential improvement has been made in it during the last 50 years. A great deal of research work has been done on the whole problem, but progress has been slow due to the complexity of the reactions taking place and variations in the composition of the juices. Recent work indicates that colloidal chemistry may play quite a part in securing a greater elimination of impurities, some of which are colloidal. The problem is now being attacked from this standpoint, with some promise of ultimately reducing the loss of sugar in the form of molasses.

Many other problems of almost equal importance remain to be solved. After some years of research work in the beet sugar industry the writer is firmly convinced that more fundamental research will yield very handsome returns in increased production efficiency and greater yields of sugar.

Denver, Colo.

Machinery Cannot Displace Human Factor in Food Products Industry

By F. E. Barbour
Vice-President, Beech-Nut Packing Co.

IN THE food products industry, perhaps to a greater degree than in any other, the main element of production efficiency lies in the human factor.

Give six cooks the same recipes, the same materials, the same utensils and the same kitchen; give them free rein, let them all work at the same time—and you'll get six different results.

Enlarge this kitchen to the proportions of a modern food products factory equipped with the most scientific methods and machines, and you're face to face with the same problem—how to train the people to use to the best advantage the tools given them so that a uniformity of product results.

To select and train these workers properly is a big problem. A bright, sunlit factory with ideal surroundings and pleasant conditions attracts plenty of recruits, especially if word goes out that "it's a nice place to work." But the sifting-out process requires time, patience and expense. Personal neatness, deft fingers, accuracy and speed all count. But proper credit for each, with equal debit for lack of any one, must be regulated sharply and with a kindly spirit.

Foods, to receive the approval of our pampered American palate, must reach the manufacturer's highest standard in every package. Folks are more finicky about the way their food looks and tastes and smells than any other commodity of daily use.

Machines may make the products, chemists may announce the calories contained, but, like the pancake artist in the restaurant window, the person concerned in the preparation is the greatest element of all.

Each manufacturer must work out his own methods of training, but all center around one big idea—treating folks well. The physical properties of the plant, the traditions of the product and the ideals of its maker quickly tell the worker what is expected of him. Encouragement to study his fellow workers who progress most rapidly teaches him how he may advance.

Bulletins giving testimonials of satisfaction from users of the product impress him with this personal responsibility. Occasional trade gossip, such as acceptance of the product by large users, gives him a hint that the management appreciates his efforts as well as those of the sales force.

A suggestion box asking for his ideas makes him feel that he is more than a mere machine. An inside house organ, the company library, varied recreational and beneficial activities which come under the head of "welfare" work all serve to train men and women for the best interests of the company and its products.

Improve machines as you will, all is worthless unless the operators are better than the machines. Manufacturers of food products are wide awake to the importance of cultivating their personnel. Any reader of *Chemical & Metallurgical Engineering* may satisfy himself along these lines by a visit to the plant of any well-known and nationally advertised food product, and talk to the people themselves.

The success of the product is measured only by the satisfaction of the people who make it.

Canajoharie, N. Y.

Management's Reluctance to Use Technology in Wood Distillation

By F. J. Root

FOR a term of years the writer was firmly convinced that his own industry, wood distillation, was being managed as a whole in the most unprogressive way, particularly in the attitude of its owners regarding research and improved methods. As my horizon broadened I came in rather intimate contact with engineers, chemists and laymen in other lines of endeavor who were equally sure their own industry was least progressive. So it appears the super-conservative policy has been unfortunately general; too often when a chief executive was approached with an improvement in efficiency he at once turned it down, saying in effect, "I would as soon try to pick the lock on a morgue."

This managerial attitude has led to some highly humorous disease pictures in industry. One illustration may prove of interest. The gum turpentine business in our Southern States is very old and quite extensive, consisting of scattered plants each of which must have a copper still. Up to about 10 years ago these were actually run without the use of a thermometer. But finally an enterprising man took an ordinary thermometer, put a few simple marks on the scale for convenience in remembering the boiling point and went out selling one to almost every still owner and charging them something like $100 each!

These Southern stills had been in operation for three generations and during that time there was not enough accumulated enterprise to make use of a common thermometer. Hence one must commend the man who introduced heat-measuring equipment, even though he did charge twenty times the market price.

Manufacturers are inclined to believe in authentic history if it is not technical. Why not accept the technical, provided it is well compiled and reliable? The gum still incident cited is comedy, but it is also tragic history, because all those years the stills ran without thermometers and it meant a loss of goods—probably 10 per cent of all the turpentine. This in turn meant the unnecessary cutting of many thousands of acres of prime forest.

Plants can run without research just the same as

gum stills can run without a thermometer, unsatisfactorily; just the same as an army unit can go into action without its observation balloon, blindly.

Wood distillation can do without either improved methods or research if the management is willing to keep a large percentage of its plants idle, as is now the case. Likewise it can do without raw material provided always it does not care to operate its plants.

Research is a business. Even that overlord the banker is coming to recognize this, and there are other substantial indications that the day is at hand when the ultra-conservative elements will be swept into the discard and when the technically progressive will be in the ascendant.

Chicago, Ill.

Mechanical Improvements vs. Fundamental Research in the Leather Industry

By John Arthur Wilson
Chief Chemist, A. F. Gallun & Sons Co.

MANY complicated processes of unknown mechanism and a vast amount of time and labor are involved in the manufacture of leather, making this a fertile field for studying methods of increasing production efficiency. The most obvious means of lowering production costs is the replacement of manual labor by mechanical appliances which perform the work more quickly and reliably and utilize sources of energy much less costly than man power.

In many plants the tanning of sole leather requires 6 months or longer, during which each hide must be handled many times. When enterprising mechanics began to exploit this field, the sole leather tanners were not slow to adopt the use of time- and labor-saving devices wherever it was clearly demonstrated that the introduction of new systems effected a real saving in the cost of production.

But the writer believes that the opportunities for increased production efficiency lie less in mechanical improvements than in fundamental chemical research. Six months of work is required to tan sole leather in many yards simply because the tanners have a process that requires it and they do not know how to get the same results in any less time or with any less work. Mechanical improvements may make the process operate more efficiently, but they do not change the process itself.

Fundamental chemical research on tanning has been in progress at Columbia University during the past 4 years and many valuable papers on the subject have been presented before the Leather Division of the American Chemical Society at its annual gatherings. Yet how many tanners today appreciate that the rate of tanning, the rate of penetration of tan liquor into a hide, the degree of plumpness of the leather and its color and smoothness are all controllable chemically? Much of the work that men are now striving to do more efficiently by mechanical means will probably be eliminated entirely through fundamental research.

Although a campaign of education may be necessary to show the tanners what chemistry has to offer the industry in the way of possibilities for increased efficiency, it is scarcely likely to succeed unless it clearly differentiates between the value of the science of chemistry and the mental limitations of many of its followers. A British tanner once explained to me how he had proved that chemistry had no application in his plant. He hired a young graduate for the munificent salary of 30 shillings per week and sent him straightway into his color room with the challenge to show how chemistry could improve his system for dyeing leather. The young man naturally was helpless and the tanner tolerated him only for a few weeks. Still the tanner did not begrudge the loss of the few shillings it had cost him, because it set his mind at rest on the subject of applied chemistry in the tannery.

What the industry needs are the most highly trained physical chemists available. If such men enter the industry with a reasonably clear appreciation of the truly remarkable development of the art of tanning and learn to use their training to supplement, rather than replace, the art of the tanner, the result will probably be an increase in production efficiency greater than would ever be possible by the introduction of mechanical improvements alone.

Milwaukee, Wis.

Intelligent Scientific Control Essential to the Lime Industry

By Warren E. Emley
Bureau of Standards

CONTROL—intelligent control—is undoubtedly the answer to the question, What can the lime industry do to increase its production efficiency?

Ten years ago there were few limekilns making more than 3 lb. of lime per pound of coal. Today there are few making less than 5. Fuel efficiency doubled in 10 years! This is an achievement of which any industry might justly be proud.

This was accomplished because competent engineers made a careful study of kiln design, fuel combustion, heat distribution and temperature control. The facts which were discovered were put into practice. Pyrometers and chemists have come to be important factors in the operation of a lime plant.

While congratulations are in order, one should remember that the fuel ratio theoretically possible is about 14 lb. of lime per pound of coal, so that there is still room for further improvement.

However, fuel efficiency is only one item of production efficiency. The sale of the product should be studied just as carefully as its manufacture has been, and should be subjected to the same degree of "intelligent control."

Years ago one used to hear statements like this: "The stone in my quarry is not so pure as that of my neighbor. I can't make as good lime as he can, but it is not my fault." The modern version of this story shows a radically different viewpoint: "My neighbor makes a good building lime, but he is getting only $6 a ton for it and he can operate only 8 months a year. My stone will not make good building lime, but it is much better than his for making bleach. I will sell it for that purpose, where they pay $9 a ton and the demand is steady throughout the year."

The modern lime manufacturer has discovered the fact that no lime can be called good or bad unless its use is considered. A lime which is excellent for one purpose may be unfit to use for some other purpose. For this reason it is necessary for the lime manufacturer to study the way in which his lime is used. It is only through a thorough knowledge of his customers' requirements that he will be able to make the best lime to meet those requirements.

The old idea was to make the "best" possible lime from the stone available, the definition of the word

"best" being based on the opinion of the lime manufacturer. This lime was then sold for a variety of purposes, for only a few of which it was suitable. The modern idea is to let the customer define the word "best"; to study his individual needs, and change the process of manufacture in such a way as to produce the kind of lime best suited to meet those needs. This, of course, involves accurate and continuous control not only of the manufacturing process but also of the sales organization, to see that each particular kind of lime is used only for the purpose for which it is best adapted.

Intelligent control includes not only the control over the manufacturing process and of the sales but a far more important idea: the lime manufacturer must control his opinion of the quality of his lime, and make it subservient to the opinions of his customers.

Washington, D. C.

Economic, Not Technologic, Considerations Govern in the Gas Industry

By R. B. Brown
General Manager, Milwaukee Gas Light Co.

THE technical situation in the gas business today is confused. There are so many conflicting views as to the future that any authoritative statement as to what can or should be done is not possible. But in general all will agree that economic, not technologic, considerations govern the industry at present.

Gas companies are not financially in a position to make drastic changes in plants. Rates are believed by the public to be exorbitantly high and are known by the operators to be inadequate to attract new capital that is needed to take care of anything more than needed actual extensions of plant and distribution systems.

I believe a great deal of progress will be made in the design of carbonizing equipment along lines that have not been given any thorough tryout as yet because of the fact that up to very recently drastic heating value and candle-power requirements prevented any such thorough tryout as is necessary to develop and perfect any new method of handling. However, we shall have to feel our way, partly because of ignorance of possibilities, but more because of the limitations financially.

The future of the business from the standpoint of the volume of sales is tremendous. We don't any of us know anything about the saturation point. So far as our ability to supply is concerned, it will be taxed for years to come along the lines of present endeavor. But during such a period as this, to revise all methods of manufacture and distribution, to amortize the capital thus involved and at the same time to provide earnings to attract new capital in enormous quantities—well, it is a proposition that can't be "put over."

The Question of Rates

Rate structure is another subject which is very much to the fore. The obsolete rates now generally in effect in the sale of gas in this country permit the extremely small user (who is increasing in numbers through modern methods of living in apartments and taking meals elsewhere) to abuse the privilege which, under these rates, he has of compelling the company to maintain a meter, service and a readiness-to-serve without any compensation or in some cases with partial compensation for the actual cost.

The difference in the investment required for different types of consumers, with their varying demands and load factors, is so tremendous that this problem alone will probably receive a great deal of attention for years to come before any even approximately adequate solution is reached.

Reduction of Investment Per Unit of Output the Problem

The technical problems are not being neglected in the meantime, but they do seem insignificant in contrast with the great problem of fixed charges on investment. What we need is greatly to reduce the investment per unit of output. Some progress has been made, but much more is essential to reduce the capital charges per thousand feet of gas and per unit of byproducts made.

Complete gasification of coal promises much in this direction, but as yet this means is limited by official requirements as to the heating value of the gas. Others argue for low-temperature carbonization as a cure-all. But there one finds a technologic limit. In any event these or some other such schemes must be evolved which will free the gas from the excessive burden of interest, depreciation, amortization, taxes and profit on the large investment now required for each thousand feet of gas sold. "Cheap" gas service cannot possibly carry such a load.

The byproduct possibilities of the industry suffer quite as much as the gas. They may, with high capital charges, even reach the point of creating losses rather than added net income. In fact, in many cases now there are plants which do not find it practicable to recover some available byproduct, because the investment and labor charges per unit made preclude profitable marketing of them.

Real progress in the gas industry will, in the end, certainly come from improved technology. But those who contribute to this progress must give quite as much attention to reducing investments and unit costs for labor as to yields per ton of coal or B.t.u. per foot of gas. The dominating factors in the industry will certainly for some time be financial and economic.

Milwaukee, Wis.

A Co-operative Research Program for the Vegetable Oil Industry

By L. M. Tolman
President, American Oil Chemists' Society

IT IS the opinion of the writer that the most important development of the past year and the thing that gives greatest promise of increasing production efficiency in the edible-oil industry is the plan of co-operative research along the lines of the fundamental questions involved in the refining and handling of edible oils. The joint research committee of the American Oil Chemists' Society and the Interstate Cottonseed Crushers' Association, working in co-operation with the United States Bureau of Chemistry, has under way some very important investigations regarding the composition of the non-fatty substances in crude cottonseed oil and other crude oils. This investigation is undoubtedly fundamental in the advance of our refining methods which at the present time are based on the more or less empirical methods adopted 10 or 15 years ago as the result of the cut-and-try experiences of practical refiners. Progress in the production of edible oils will undoubtedly be along the line of real fundamental research in refining methods. At the present time refining losses are admittedly much higher than they should be.

The research work which can be carried on by the

governmental departments is necessarily limited, and while the results so far obtained are going to be of great value to the industry, it would appear that the edible-oil industry itself would make much greater progress if it could organize its research work in a co-operative way, either by the establishment of research organizations supported by the industry or by the endowment of fellowships in the existing research organizations. It is the writer's personal opinion, however, that much more important results could be obtained, and they would be obtained in a shorter time, if the edible-oil industry of this country would establish a research organization of its own for studying the problems in regard to the refining and handling of crude vegetables.

Laboratories, Wilson & Co.,
Chicago, Ill.

Further Improvements in the Soap Industry Must Come From Chemist and Chemical Engineer

By Martin Hill Ittner,
Chief Chemist, Colgate & Co.

I DOUBT that there is any important industry that does not offer opportunity for increased production efficiency. As there are believed to be large fish in the sea still waiting to be caught, so too there are, no doubt, great improvements in industries awaiting the discerning eyes of wide-awake chemists and chemical engineers.

The soap industry has been subject to some intelligent investigation during recent years and most of the methods now used are good. Within the limitations of a brief statement such as this, it is possible to indicate only a few of the things that may lead to future improvements.

Small units require more labor and more steam for a given amount of material handled than large units, and the large soap pans in use in some factories show that certain manufacturers have already learned this fact to their advantage.

Just as open and closed steam coils have proved immeasurably superior to fire heating, and as pumps are more efficient than ladles for handling raw materials and products in course of manufacture, so automatic machinery has been used to advantage and its additional use and improved types thereof will continue to make production more efficient.

Physical Chemistry in Soap Making

As to the actual manufacture of soap, it would be difficult to beat the quality of material turned out by the settled soap process when properly carried out. This process gives two distinct phases or layers, the upper of which may be made remarkably free from excess alkali and other impurities. The only drawback to this process is the time it takes and the fact that approximately 20 per cent of the soap produced goes into the lower phase, or nigre, along with excess alkali and impurities, and this necessitates the reworking of an appreciable amount of the product.

If the settled soap process is to be improved, rather than replaced, it will have to come through a study of the physical chemical conditions that will promote the complete formation of the two distinct phases and their rapid separation. A low viscosity in this change is a desideratum, whether it is obtained by changes in composition or by a more perfect temperature control. The composition of the phases is influenced by the mutual solubilities of all the substances present and these are influenced by the temperature, so, as a matter of fact, a control of viscosity and consequently more rapid and more complete separation of the phases can be obtained only by a proper control of the composition of the whole mass and the temperature.

A number of years ago I found that the soap phases could be completely separated in centrifugal machines and I aimed to run them through a suitable machine to effect at once the continuous separation that has always required a considerable amount of time. So far I have not seen the machine that would compete with gravity settling, considering together effectiveness, capacity and cost.

It is possible to make good soap without the formation of nigre, but it is more difficult to get uniformity and high quality and is more expensive for labor and control than the settled soap process.

Other Lines for Improvement

The economical production of soap requires a study of the selection, treatment and apportioning of raw materials, fats, oils and alkalis, and their control through the stages of manufacture up to the production of finished soap and glycerine. There are few places where at least some improvements are not possible all along the line.

In the manufacture of toilet soap a big advance was brought about by the rapid, continuous, clean drying made possible by the Cressoniers driers and later by the several other driers using the same principles of chilling the soap on cooled rolls and sending the ribbons over endless woven wire belts through a drying chamber. An automatic or other suitable simple control of the amount of drying or percentage of water in the finished soap would add to quality and efficiency.

Soap powders are being produced on a large scale and quick and efficient methods for their manufacture are being worked out and adopted.

Jersey City, N. J.

How Process Equipment Aids Production Efficiency —Pointers for the Purchaser of Equipment

By O. S. Sleeper
President, O. S. Sleeper & Co., Inc.

IT IS essential, in all manufacturing lines, to increase production efficiency and reduce manufacturing costs. This end is largely achieved through judicious equipment purchase and efficient operation of the equipment purchased.

The tendency of the users of equipment is to buy on price or to find used material that will do. In most cases both these methods result in unsatisfactory operation. Only apparatus containing all the elements necessary for the manufacture of the product and constructed of material best suited for the purpose should be considered; and adaptability rather than first cost should be the main consideration.

If this course is followed, satisfaction should result. This satisfaction will extend beyond the purchase and installation of the equipment. It will please the workman, thus making his work more tolerable, resulting in increased production, better quality of product and more satisfied workers.

It is often a question with the manufacturer of chemicals as to what apparatus he should use; and in the effort to find what he requires, or can use, he peruses the advertisements. With few exceptions, this is his

only method of locating the manufacturer of equipment, and is the proper method. However, the advertisement is generally brief, and perhaps does not contain the information he requires.

It is necessary, then, that he write to the equipment firm for this information and for prices. He sends his inquiry, which is also brief; and, in reply, he receives a quotation and a request for additional information. This is not satisfactory, as the quotation does not cover the requirements, and further delay is caused.

These delays and unsatisfactory methods may be eliminated to a large extent and better and more satisfactory equipment furnished if the secretiveness which surrounds most chemical plants be set aside and confidence placed in the equipment manufacturer. If the chemical plant furnishes designs, then the reliable manufacturer will hold such designs in confidence. Often the standard equipment will do or it may be modified to suit specific requirements, and such modifications could be made by the builder better and cheaper if he were informed of what is necessary. It must be kept in mind that an advertisement cannot convey the complete information necessary for the final selection of equipment, as it does not explain all details of each machine.

In a majority of cases it is important to give the equipment manufacturer full information regarding the material to be handled to enable him to select from his standard designs or to make the special design required for the purpose.

This is not meant as a criticism of present methods, but is intended to convey the importance of closer relations and a greater degree of confidence between the manufacturer and user for the best interests of all concerned.

Buffalo, N. Y.

Improvements for Production Efficiency in the Glue Industry

By Jerome Alexander

IN common with other industries, increased efficiency in glue manufacture must be along lines which may be classified under two general heads: Avoidance of waste and production of an improved product. Under the first of these come power plant and fuel economies, savings in freight and handling charges, etc., which are not peculiar to the glue industry.

Steps in Process Where Improvements Are Possible

Following the raw material step by step through the process, the following points should be considered in connection wih the production of an improved product.

Receiving and Preparing Glue Stock. Avoid unnecessary rehandling and save labor by utilizing mechanical appliances. Shredded hide and crushed bone or osseine may be pumped with water or handled by bucket conveyors instead of by the manual methods still employed in many plants. By bringing the limes to the proper H-ion concentration with caustic soda, the time of liming may be shortened without injury to the stock.

Washing Glue Stock. An improvement over the old cone and paddle wheel washers, which have been in use for years, seems called for. Circulation of the stock by a screw conveyor through a trough against a stream of water seems to be an interesting possibility, for the washing would proceed continuously rather than on the batch principle. A new German washer having two vertical shafts with arms is emptied by a bucket elevator.

Boiling. Most factories depend mainly upon convection to distribute the heat, and this generally results in local overheating, besides protracting the process. The more general introduction of circulating pumps, used in some plants, should be advantageous.

Evaporation. The vacuum evaporator is so highly perfected today that lack of capital or insufficient capacity is the only excuse for not having an efficient unit—a good illustration of what scientific engineering practice can do for an industry. However, priming must be avoided or glue will be lost with the condensate.

Chilling, Cutting, Spreading and Drying. Although for years the attempt has been made to combine these into one operation, none of the older systems proposed, even that of Peter Cooper Hewitt, has survived. Most promising is the Kind apparatus, which is said to chill, cut and spread an evaporated glue liquor within about 20 minutes after its receipt. The apparatus is automatic and effects a great saving in time and labor.

Speedy drying of glue is important, otherwise an expensively large dry room is necessary to avoid a "neck" in the process. The netstacks should fit the room closely, otherwise the heated air will get by without taking its full quota of moisture.

The Ruf system, recently introduced in Germany, delivers a concentrated glue froth to a hooded steam-heated revolving drum over which a draft of air is forced. The finished glue in powder form is scraped off by a knife. Vacuum drum driers are also used to produce glue powder, but this form of product is objected to by some consumers, without good reason in many cases. Much trouble and expense can be saved by consulting firms or engineers who have had actual experience in drying glue.

Byproducts. Some plants do not use or give proper attention to catchbasins and lose grease-containing material. Others again lose grease in their fertilizer tankage, where it is rather a detriment. For some uses grease improves glue, and if the market for glue is higher, some grease may profitably be left in the glue.

Producing Better Glue

The basic principle is to get the glue dissolved out of the stock and dry it as quickly as possible and with minimum exposure to heat, both in point of time and degree, and without undesirable agitation. The observance of the principle requires attention all along the line—proper plumping of the stock to insure speedy solution; boiling at as low a temperature as possible, yet balancing temperature against time of boiling; evaporating without overheating; then chilling quickly and drying to avoid bacterial attack. Since the importance of the effective reaction of glue (hydrogen-ion concentration or p_H value) has been shown to affect its viscosity and water-absorbing power vitally, this should be more carefully adjusted than has been done in the past. Iso-electric gelatine which absorbs only 7 or 8 parts of water may absorb up to 40 parts at a p_H of about 3, though this degree of acidity is excessive.

All told, it pays to use the best apparatus and employ the best brains. But there is no substitute for common business sense. It is not profitable to produce an improved product at a cost which exceeds the added selling value.

Ridgefield, Conn.

More Efficient Distribution for the Products of the Chemical and Allied Industries

Sales Executives and Others Comment Frankly on the Marketing Problems of Their Businesses and Offer to Support Increased Production Efficiency With Better Directed and More Intelligent Selling Methods

RECORDED among the findings of the Joint Commission on Agricultural Inquiry is the conclusion that in the case of many of the basic commodities of commerce more than half of the ultimate cost to the consumer is directly chargeable to the agencies of distribution. This is not a particularly novel discovery in itself, but it hints at a state of affairs to which industry can well give serious thought. If the gap between producer and consumer is allowed to absorb 50 per cent of a commodity's cost, we can very profitably forget production for a moment and give attention to the disproportionate cost of distribution.

To say that a parallel condition obtains in the chemical and chemically controlled industries, however, is not to speak the truth. No such spread exists in the case of these basic materials, sold from industry to industry rather than from industry to the individual consumer. Nevertheless these industries offer much to justify a serious consideration of their selling problems. Many of the mainly chemical industries are comparatively young and during the period of their rapid growth every effort was made to solve the problems of production. The same intensive and sympathetic study which other industries have given to distribution has often been neglected in the zealous endeavor to lower the costs of production.

In the dozen or so brief messages that follow it is evident that our technical executives are already solving the marketing problems of their industries. Treatment is given such varied subjects as technical service, direct selling, open prices, market stabilization, standard specifications, elimination of excess varieties, the tariff and transportation. Improvement along most of these lines means lower costs to the consumer, whether he purchases chemicals directly or the products in which they are used. Industry as a whole will profit when increased production efficiency is supported by well-directed and more intelligent distribution.

A Higher Plane of Chemical Salesmanship

By Burton T. Bush
President, Salesmen's Association of the American Chemical Industry; President, Antoine Chiris Co.

NOW that the fine chemical industry has taken root on American soil the problem of closer co-operation between the source of production and the ultimate consumer is going to be solved to the advantage of both. Research will cease to find sympathy alone with the chemist; research will be carried clear through to the ultimate user of the chemicals produced. The American manufacturer must now recognize this as an integral part of the chemical business in America and must begin to arrange for it in his yearly budget.

I am a thorough believer in the fact that one day a chemical salesman's value will be based on his knowledge of chemistry, that he will step to his place as a possible counselor for the trade consuming his products, and his ultimate value will be in his ability to suggest. Having, as he will, his own personality and individual way of obtaining a result, he will be fearless to allow his objective to be known, because the objective will cease to be a secret of the concern he represents.

America takes hold of the chemical industry at a time after every marketing method is apparently known and has been tried. To my mind there is but one great method left, and that is to take the secretiveness and mythology out of chemistry, giving the American consumer the benefits of the knowlege of the producer, all of which will naturally result in a better co-operation.

In conclusion, I have no hesitancy in stating that the essential oil, aromatic and fine chemical industry of the United States will demand that open scientific research be employed in every phase of its work. Then quality will be known and appreciated and likewise it will be demanded, and the final proof of success of this industry will depend on how well the chemical manufacturer keeps the public in his confidence.

New York City.

Intelligent Distribution of Crude Coal-Tar Products

By David W. Jayne
Jayne & Sidebottom, Inc.

INCREASED efficiency through more intelligent distribution can certainly be obtained in the case of the so-called coal-tar crudes. This term has been very freely applied to the directly recovered products from coal tar in refined condition suitable for the manufacture of such products as dye intermediates. The manufacturing processes permit of considerable variation in the purity of the finished products, so undoubtedly what is most needed is an accurate knowledge of the requirements of the consumer as to quality and the corresponding price limitations.

An intelligent understanding of this question involves the use of experienced and "technically intelligent" salesmen; it also demands frankness on the part of the buyer of these products. It has been claimed by many buyers that the refined coal-tar products, such as benzene, toluene and naphthalene, are not as pure as those supplied to the German manufacturers, and this is probably true, but the problem is to increase the purity without unwarrantably increasing the price. Just what is needed in the line of quality specifications can be determined only by frank and intelligent discussion between buyer and seller, coupled with an equally frank understanding of the additional costs of such improvements in quality and the possible increased value to the buyer.

Prices are sufficiently open so that this, I believe, is not an essential question in the sale of this class of

products. Buyers and sellers pretty generally know at what prices others are buying and selling. These products have not been and are not sold on a basis of all the salesmen can get for them, but rather on a fixed price-list basis.

The production department must also have confidence in the accuracy of the reports of the salesmen. Too often salesmen recommend changes in quality or price which the production man recognizes as unattainable and which were "put over" on the salesman by some ambitious buyer. If the salesmen are men of technical training with experience and are in the confidence and in touch with the factory, then production efficiency can be increased by the intelligent exchange of information between sales and production departments.

All this can be summarized in a few words about as follows: Confidence and co-operation between the sales and production departments of both buyer and seller mean increased efficiency of distribution as well as production.

New York City.

Autumn Prospects in the Dye Industry Are a Matter of Conjecture

By Giles Low
Sales Manager, Newport Chemical Works, Inc.

IT IS no easy task to make an estimate of business conditions for the fall in the dye and coal-tar chemical industries. True, they must be good or bad; but definitely to say which precludes a foresight into the decisions of that inexorable body at Washington—the Sixty-seventh Congress. Not only for fall, but indeed for our whole future, does the making of business conditions lie now with our government, and to indicate to it what is right is at present our most responsible task.

The United States owes a debt to its chemists, who have striven diligently during the last two hard years, and to the financiers who have backed them. Moreover, she owes to our citizens the insurance of the safe and prosperous future which only a substantial domestic chemical industry can bring.

Protection of an Essential Industry

So much has already been said and written of what the chemist has done for us as a nation in the way of inventing and manufacturing medicines and drugs, as well as dyes and foods—necessities normally unappreciated—to say nothing of explosives in times of war, that a repetition of the vital importance of the industry is almost unnecessary here. Whether we shall maintain the protection and enjoy the fruits that our new chemical supremacy has given us, or humbly give them up to our erstwhile enemy, is today in the hands of Congress.

If the outcome again puts us at the mercy of Germany, business will be bad in more ways than one and for more than those now interested. If, on the other hand, some adequate protection is granted, a condition even somewhat better than normalcy will obtain. Our universities will not have educated chemists in vain; our financiers will not have wasted their vast sums invested in the industry, and our most promising infant in the industrial field will grow to be our most useful big brother.

Passaic, N. J.

Straight Talk Needed Between the Oil Producer and Consumer

By Otto Eisenschiml
Manager, Scientific Oil Compounding Co.

THE PROBLEM of marketing special oils is one that is more inherent in the buyer than in the seller. These oils are made to fill a special want not covered by standard grades of oil on the market, and one would expect to have possible customers talk frankly and straight to the point about their troubles. Unfortunately, this is far from being so. They come to the manufacturer like a sick man to a doctor, but what they want is not a cure for special ailments at the doctor's discretion, but a special 10-grain white pill to come in a blue box with a yellow label. Only a few days ago a manufacturer was asked to supply a certain cold-pressed vegetable oil. Being fairly honest, he refused even to quote on a commodity existing only in the minds of some buyers and in the mouths of imaginative salesmen. During the discussion that followed the manufacturer found that all he had to do was to supply a fairly clear oil of low acid value and good drying power—the cold-pressing having been lost in the shuffle.

Specifications for special oils, printed and otherwise, are full of arbitrary and unnecessary points, such as the one mentioned. The psychology of the buyer seems to be that the more trouble and expense he can put on the manufacturer the better the goods will be for himself, and he therefore tries to prescribe what should be done rather than what should be accomplished. Almost all specifications on linseed oil demand that it be aged by tanking. What is really wanted is a clear oil, and of all the methods possible to get this result, such as filtration, centrifugal machines, etc., tanking is the most uncertain and most expensive of all. And yet we have constantly to contend with such people and others who demand that a varnish be thinned with turpentine when they mean that they want a high flash point, that a paint oil contain no rosin when they mean that it should not liver with white lead, and so on *ad infinitum*.

I do not know whether or not the special oil field is different in this respect from other fields of endeavor. But the fact remains that, just as straight line is always the shortest distance between two points, so a straight talk between producer and consumer is the best basis for all specifications.

Chicago, Ill.

Knowing the Requirements of the Consumer of Vegetable Oils

By Henry G. Perry
Sales Manager, Cook & Swan Co., Inc.

WE ARE all interested in increased production efficiency. The theme is well chosen. Among other things, it would imply power on the part of the distributor to retain a clientèle secured by strength of salesmanship. The day has gone by when we might have been able to give a customer something "nearly as good" as that which he requires. The efficient method of distribution today is to sell your article on a guarantee of satisfaction, whether it be oils and greases for technical trades or for the refinery. Salesmanship, in itself, is a part of the business which cannot be treated lightly. But salesmanship commences only when the product is salable. In other words, the quality of a product must stand before the art of selling. The man

with the best product today will get the order. The consumer's troubles should be the troubles of the supplier, and the supplier should base his products on the requirements of the consumer. We must forget the product which was nearly as good and put in its place the product with which the consumer can register complete satisfaction. A house with a hundred satisfied regular clients is better than one with five hundred spasmodic inquirers.

New York City.

Eliminating the "Fly-by-Nights" in the Chemical Industry

By Milton Kutz

Manager of Sales, The Roessler & Hasslacher Chemical Co.

AS IS DOUBTLESS the experience of others in the chemical industry, the firm with which the writer is connected frequently finds itself underbid by importers and other firms whom we would like to characterize as "fly-by-nights" and who having had only a few years' experience, either do not realize or do not care whether their goods are suitable or meet the specifications of the particular consumer or industry for which they are intended.

On the other hand, the service given to this trade by the older chemical houses is the result of many years of experience in production and actual use of the products they produced. The knowledge derived therefrom is gladly passed on to their customers. However, no legitimate enterprise can continue to maintain a large sales organization and give service unless there is some margin of profit. A mighty endeavor to sell, which has become prevalent in many branches of the chemical industry, has been the cause of the receiverships in bankruptcy which have been occurring so frequently. The "return to normalcy" phrase has become something of a joke. It will never be accomplished until some people thoroughly learn their lesson that overhead must be considered in their selling price. Not until more chemical firms do this will a real stabilization of the market be attained.

New York City.

Resale, Turnover and Volume—The Problems of the Paint Industry

By H. D. Whittlesey

Vice-President and Managing Director of Sales, The Sherwin-Williams Co.

THE three words resale, turnover and volume sound the keynote of the endeavor we must all put forth today.

What's the answer?

A keener sales activity. If our products are better than the other fellow's, then we have a right to expect corresponding increases in volume. It behooves us to present our proposition attractively, or the other fellow will outsell us.

We must have better kept plants, better production, better looking products, better packing and shipping, fewer mistakes down the line.

Warehouses must be well located and efficiently serving the territories they are intended to serve.

Salesmen must give a type of service never before required to such an extent. There must be less duplication. There must be more emphasis on the goods and what they will do; clerks must be better educated to sell—they must know the whys and wherefores of quality, ingredients, purposes, etc. Price cuts little figure if the resale of the product is in the right hands. Put a Cadillac in poor dealer hands and you will immediately boost the sale of Lincolns.

Creative Salesmanship Is Essential

New avenues of sale must be developed. We cannot keep taking business from our competitor without building new business and new markets. Creative salesmanship is the need of the hour. It must be specific, educational and thorough. So must the advertising of today. One cannot continue advertising for "general results" or his results will be very general. He must talk his product in terms of what it will do, how it will fit into the scheme of things, and it must be told in a human, readable way. Only a few people are relatively interested in mechanics; masses of people are interested in the everyday stories of life and living.

The sales department must know who is buying its goods; who used to buy and stopped; why did they stop; what new trade is being added to the books; what dealers are being added; what dealers are being dropped; how is the volume changing geographically and why; what important towns and territories are undermanned or not manned at all; what is each territory producing per man per day per dollar of cost; what dealers are going ahead and what dealers are standing still and why; is the salesman taking orders or is he helping to resell for the dealer to make way for more goods; what classes of trade are being called on daily and what classes are being neglected; is too much time being spent on unproductive things.

We have a man-sized job ahead, but the victory will go to those who produce well, distribute wisely, turn over their investment frequently, sell hard and render a service to the buying public.

Cleveland, Ohio.

Marketing and Distribution Problems of the Alcohol and Related Chemical Industries

By B. R. Tunison

Manager of New York Sales, U. S. Industrial Chemical Co.

MARKETING and distribution problems in the alcohol and related chemical industries are complicated primarily because of the nature of the principal raw material in these industries—namely, alcohol. This material is subject to very strict regulation and control. Since the passage of the national prohibition act, the regulations and red tape have become so great as to interfere seriously with business using alcohol for industrial purposes. Not only have the users been subject to various laws, rules and regulations, as well as arbitrary rulings (not based on law or regulation) on the part of federal officers, but the manufacturers of alcohol have been unable to develop and extend their business in accordance with the law which provides for "an ample supply of alcohol and promote its use in scientific research and in the development of fuel, dye and other lawful industries."

One of the greatest problems facing the fine organic chemical manufacturers in the United States at the present time is that of technical service. Many phases of these industries are new to the United States and the utilization and development of the products call for definite technical information and advice. In the first place, it is difficult to obtain men who are able to render such technical service, and in the second place, when

such advice and service are given, it is not always easy to convince the user that the product and method of utilization indicated are to his best advantage. This inertia is due largely to the operation of some industries by rule-of-thumb methods rather than modern technical control.

Probably the most depressing factor and the one interfering most with the proper development of our American chemical industries at the present time is the tariff situation. It is impossible to develop sales, distribution, production or anything connected with a healthy chemical business when the manufacturers do not know from one moment to the next whether they are to be protected in their efforts or whether they will be subject to the ruthless competition which is the inevitable result of not keeping out of the country products which will be sold at prices far less than the cost of production by American manufacturers.

A factor which is bothering a number of manufacturers in these industries is the fact that during the war a capacity for the production of certain products was developed which is in excess of the normal consumption during peace times. Strenuous efforts are being made to develop new markets for these products in order that production can be increased to the approximate capacity so that a moderate cost of production can be maintained. This puts tremendous pressure on marketing and distribution activities in order to reduce the cost to a satisfactory level.

Although many of our American chemical industries are passing through very trying times, there is no question that they will be successful and able to compete in any world market if they are given sufficient time and proper encouragement and protection. Chemical industries such as we are building in the United States at present cannot be completed in the space of a few months. Therefore proper protection should be given them until by development products are improved and costs are reduced, so that these industries may succeed.

New York City.

The Ferro-Alloy Situation Beclouded by the Tariff

By J. W. Bradin
Vice-President, Dana & Co.

THE problems connected with the marketing of ferro-alloys are rather difficult to gage, due chiefly to the proposed new tariff rates and in part to the market position of ores. Ferromanganese will undoubtedly sell at a much higher price than today if the high tariff duties on ore and metal are passed. Already this is apparent by the willingness of buyers to pay a premium for foreign ore due to arrive shortly. We believe further that the expected increase in price of ferromanganese will stimulate the sale of spiegeleisen.

The price of ferrosilicon will probably not rise in step with the higher protective rates, due to the largely increased manufacturing capacity for this alloy, which potentially at least should act as a restraint to any substantial increase in price. In spite of a much higher tariff on ferrotungsten, we expect only a gradual increase in price, due to the very large spot supply of ore which is hanging over the market. On the other hand, ore can be bought today below the cost of mining, a condition which is not likely to continue. Marked changes in price for either ferrochromium or ferrovanadium are not expected in the immediate future.

New York City.

Distribution of Chemicals in Foreign Markets

By C. R. DeLong
Chief, Chemical Division,
Bureau of Foreign and Domestic Commerce

THE QUESTION of intelligent and effective distribution of American chemical products in foreign countries is one that is of deep interest to the Chemical Division of the Bureau of Foreign and Domestic Commerce. The marketing of chemicals outside of the United States presents problems of a character differing from those met with in domestic markets. It is only by a close and careful study of conditions existing in the markets of each particular country that the most efficient distribution will be attained. I believe that the recently created Chemical Division will be able, through the various agencies at the disposal of the Department of Commerce, to give material assistance to the domestic chemical industry in solving these export problems.

The department, by means of its commercial attachés, trade commissioners and the co-operation of the consular service of the Department of State, can place at the disposal of American chemical concerns interested in the development of foreign markets information as to the extent of markets, the competition that is likely to be met, agencies that are qualified to handle the particular products, customs duties and commercial regulations governing the sale of special commodities.

Representatives of the department in foreign countries are constantly reporting opportunities and inquiries for the sale of American goods. These "trade opportunities" are brought to the attention of domestic firms known to the department as being interested in the development of foreign trade. In this connection a list of American firms known as the "Exporters' Index" is maintained. Only concerns which are American-owned and interested primarily in the promotion and sale of American goods are included in this list. These firms receive confidential information as to financial references, commercial reputation of the foreign firm, and other comments pertinent to the trade opportunites in foreign countries.

Dependable Trade Statistics

Another factor essential to the intelligent distribution of chemicals in foreign markets is accurate and detailed statistical information on the trade of various countries, so as to determine what share of this trade is being obtained by the United States. In order to make such statistics available at the earliest possible date mimeographed monthly statements of exports of important commodities showing the countries of destination are sent to interested firms. These special reports thus make this statistical information available considerably ahead of their publication in the Monthly Summary of Commerce and Navigation.

Detailed studies are made periodically of world markets for groups of commodities or on the conditions surrounding the markets of a particular country. These published reports can be obtained at a small expense as compared with the valuable information which they contain.

The Chemical Division hopes to serve effectively the American chemical industry in the development of foreign markets and to aid in the efficient distribution of its products in these markets by placing such information in the hands of interested American firms at

he earliest date and in the most concise form. I elieve that if the chemical manufacturer will avail imself of the services of the Chemical Division the istribution of chemicals in foreign countries will be ore efficient and there will result less waste in time nd money. With complete information at hand, the ale of American chemicals in foreign markets should e no more difficult than the marketing of the same roducts in domestic markets. The Chemical Division s always ready to receive and seeks the suggestions of omestic firms as to the nature of the information hich will be of the greatest aid in marketing their roducts in countries outside of the United States.

Washington, D. C.

The Alkali Market From the Jobber's Viewpoint

By W. F. George

President, W. F. George Chemicals, Inc.

THE SITUATION in the alkali market, particulary in the less than carload jobbing trade, continues to e very unsettled, as it has been for many months past. his seems due principally to two reasons: first, the eneral business condition, which makes it practically mpossible for the small consumers to predict intelli- ently what their requirements will be over a given eriod; second, the great variety of prices quoted by he various factors in the alkali market on this kind f trade.

The open price policy advocated by many in various ines of business would go a long way toward stabilizing he alkali market if it were conscientiously adhered to y all. However, if a pretended open price policy is ombined with underhanded cut-throat competition, no enefit will be derived, but on the contrary a situation lready bad will become worse.

If this market could be stabilized at some fair level, he consumers would gradually gain confidence in their ources of supply and would feel more inclined to con- ract ahead for their requirements instead of buying rom hand to mouth as they have been doing up to the resent time. This would result in lower selling costs, nore efficient distribution and an ultimate saving to ll concerned.

New York City.

Stabilizing Profits in the Petroleum Industry by Predetermining Market Conditions

By Joseph E. Pogue

Consulting Engineer

DURING the past 18 months the problem of stabiliz- ing earnings in the petroleum industry has received vide attention. The general feeling in oil circles has een that the extreme fluctuations characteristic of this ndustry constituted a serious liability and that con- erted effort should be made to avoid the tremendous osses arising from this source. Unfortunately, how- ver, the only noteworthy attempt so far to better onditions—the policy of price stabilization started late ast year by the major purchasers of crude petroleum— was abandoned last month with drastic price slashing nd must accordingly be adjudged a failure. Thus oday the petroleum industry is in a chaotic condition, pparently further from achieving stabilization than t any time in its history. Evidently some new methods f attack are needed.

Perhaps we can see what these new methods must e if we analyze the fundamental causes of this in- stability. The underlying causes are two in number: fluctuations in price and variations in demand. Both of these conditions are primarily beyond the control of the petroleum industry itself and thus we reach our first conclusion; namely, that the basic cause of in- stability in the petroleum industry is external and arises from the instability of price and demand in the com- modity markets upon which the petroleum industry is dependent.

The losses from these fluctuations in prices and demands are tremendous and exert a disastrous effect upon earnings and profits. For example, one of the largest and most successful refining companies in the East in 1921 showed gross earnings of only $105,000,000 as compared with $169,000,000 in 1920, due to a sudden recession in price and demand; the effect upon net profits was even more destructive, these falling from $10,000,000 in 1920 to a loss of $5,000,000 in 1921. An- other very successful company, this one both a producer and a refiner, operating in the Gulf coast, suffered a decline in gross earnings from 1920 to 1921 of $32,000,000, and the net profits of this company were $19,000,000 less in 1921 than in 1920. These two ex- amples are not exceptional; they represent, on the con- trary, two of the best and most conservatively managed oil companies in the United States.

The Crux of the Matter

The petroleum industry, in common with all other industries, has devoted no end of effort to increasing its operating efficiency by perfecting its control of in- ternal conditions. The outstanding and untried oppor- tunity lies in the direction of external conditions— conditions that are responsible for the loss of perhaps three dollars for every dollar lost through operating inefficiency. But external conditions, as we have noted, are not primarily subject to control by operating units of an industry. True; but operations can be adjusted so as to fit external conditions, in so far as the latter are not subject to direct control, and this brings us to the crux of the matter: External conditions—that is to say, prices and demands—should be charted ahead with the same care that internal conditions are analyzed and projected, and when this is done adequately the oil business can be kept on the track, even though the track itself cannot be entirely straightened.

Can prices and demands be predetermined scien- tifically? The answer, with due qualifications, is yes, but not easily nor incidentally. Not until the oppor- tunity existing is recognized and proper effort is accorded it. No, in fact, until the oil industry gets up to date in this respect and does, as a matter of course, what enterprising concerns in many other lines are doing. Then the results, though far from infallible, may be expected to raise substantially the average of accuracy with which plans can be laid and production schedules guided.

The way is open. There is no need for the best companies in the oil business to have suffered the losses they did in 1921. There is no need for the best com- panies in the oil business to alternate between over- production and underproduction, to swing perennially between a feast and a famine. The answer lies in the market place; the way to the answer is through the employment of a new tool—the analysis and use of external conditions, the predetermining of price and demand.

The Fundamental Requirements of Salesmanship in the Heavy Chemical Industry

By P. S. Tilden
Sales Manager, Lithopone, Pigments and Heavy Chemical Division.
E. I. du Pont de Nemours & Co., Inc.

LONG EXPERIENCE in the marketing of heavy chemicals has taught that each day brings its own problems, each its own lessons. Those who persist that there is a minimum of technicality in the conduct of the business suffer from the very symptoms which they claim do not exist.

A chemical salesman has nothing but his card and his personality to present to the customer. Unlike the man with a line of samples to submit and who, irrespective of personal appearances or attributes, may make sales based on the quality and price of his products, as indicated by those samples, the chemical salesman must, by his own individual force and enthusiasm, so impress his prospective customer that he becomes interested in company and products represented to him.

I have been asked whether technical knowledge helps the salesman and to what extent. It is axiomatic that knowledge of the proper kind always helps, but the extent to which it helps is governed, in my estimation, by the manner in which it is used.

Three Types of Chemical Buyers

Chemical buyers are of many types and kinds: We have the trained chemical buyer who is a part of his business, and knows its every detail from the ground up; we have the executive type who orders on requisition from his factory, with a limited degree of technical knowledge, and we have the purchasing agent, pure and simple, who will frankly confess to you that he has a "smattering" of all the products he purchases, but knows the details of the manufacture of but few, if any.

Now all these types are purchasing the same class of chemicals, highly technical in their character. The salesman, therefore, if with this technical chemical knowledge, must use great diplomacy in the manner in which he expounds his learning to the various types of buyers, or he is very likely to offend.

I have always claimed that there are three fundamentals that a chemical salesman should have at his command—viz., what his goods were made from, how they were made and what they were used for—but special care should always be used in recommending formulas, unless one is quite sure of his ground.

Each day brings the chemical salesman something of new interest—there are constantly being developed new uses for his products, so he must be wide awake and alert.

Sound Advice for the Salesman

In the days of Dana, as editor of the New York *Sun*, he had hung in his office the motto "Keep Your Eyes and Ears Open!" The chemical salesman could, with profit, bear this legend in mind. His must be an enthusiasm born of a love for his business, he must be able to convey this enthusiasm to others, he must make friends—and he must keep them. He should not be too intimate with his customers, but he must keep their respect, because his is the burden to keep them continual good-will customers of the house he represents, and he can do this, whether he can or cannot give you the formula for sulphuric acid; but if he knows it, he is so much better off.

In other words, no hard and fast rule can govern—it is the individual who can make or break his career in the heavy chemical business.

Finally, a word as to open prices. It must appeal to all that intelligent competition is far preferable to that of a ruinous character, and so if open prices will bring about the former condition, certainly they are to be desired.

The Contract Evil in the Marketing of Steel Products

By B. E. V. Luty

FOR years the marketing of finished steel products has stood in need of one great reform, abolition of the "requirement," "option," "jug-handled" or "accordeon" contract. The practice of making such contracts was established a quarter century or more ago, the late Andrew Carnegie being reputed to have been the originator of the system. The object was to tie up a consumer, so that if the consumer had requirements the mill making the contract would get the business. If he did not, the mill would lose nothing.

The principle may have been good in certain cases, but the practice was badly overdone. Mills got into the habit of overselling, on paper, in an effort to insure full operation, while buyers in turn were moved to overbuy, since when business was good, mills could not make shipments at the full contract rate.

The usual contract of this style is not enforceable. An improvement made before the war gave the seller power to cancel unspecified monthly quotas. Mills sometimes advanced asking prices simply to induce specifying on the old contracts, then making contracts for a fresh period, advancing prices again, and so on until the market became top-heavy, thus insuring an eventual break in prices.

Since the war-time control of the steel market by the government the making of these blanket or requirement contracts has not been altogether as prevalent as formerly, one deterrent factor being uncertainty as to costs. The practice should be entirely abolished, except perhaps as to contracts for relatively short periods. A definite tonnage should be bought and sold, the mill should deliver on time and the buyer should accept and pay.

Definite extras should be charged for small lots of a size or section, to cover extra cost of production. By the establishment of such extras buyers would be moved to specify larger individual quantities at a time, carrying stocks of the sizes they require in small quantities only. When steel is scarce mills charge extra for mixed specifications, but as soon as orders become scarce they forego even the most reasonable charges.

Taxing the Raw Materials of the Soap Industry

By Martin H. Ittner
Colgate & Co.

IT MAY not be out of place to say here that very large and exorbitant customs duties are now proposed for the first time on fats and oils that do not compete to any extent with our own production of fats and oils, which are exported by us in enormous quantities. This will not help the producer of American fats and oils and will necessarily increase the cost and selling price of soap.

Jersey City, N. J.

Production, Consumption and Prices

The Trend of Prices for the Principal Commodities in the Chemical Market Is Briefly Reviewed and Statistical Summaries Are Given for the Volume and Value of Manufacture, Imports and Exports

JUST as 1921 was a year of reaction from the excesses of the preceding year, so 1922 has been characterized by a slow and gradual recovery. Much of the damage incurred in the rigorous processes of deflation and liquidation has been repaired and industry in general has adjusted itself to the changed conditions of competition. All along the line there has been consistent improvement. The increased volume of production, wider distribution and growing consumption of commodities, easier conditions in the money market, higher security values, fewer business failures and better price adjustments—in fact all of these basic indexes of business activity point definitely to the fact that the corner has been turned and business is on the upward grade.

The chemical industry, somewhat slower than others to feel the effect of depression, has not responded quite as quickly to the stimulus of better times. If we are to judge from price trends, the year May, 1920, to May, 1921, covers the span of the most severe deflation. From May, 1921, to June, 1922, was given over to the uncertain process of readjustment, while the first 5 months of the current year witnessed a gradual and consistent recovery. Since last May, however, prices have shown the effect of the usual seasonal lull. It is perhaps significant to note that, as measured by *Chemical & Metallurgical Engineering's* weighted index of chemical prices, May was the high month for 1920, the low month for 1921, and again the high month for 1922.

This index number, whose course since 1917 may be found in Table I and is also shown graphically in the accompanying figure, was compiled to assist our readers in following the week-to-week trend in the chemical market. It is based on twenty-five commodities so selected as to represent qualitatively and quantitatively the principal branches of the chemical industry. The average wholesale prices for these commodities in the New York market were weighted on the basis of the total production plus imports in 1919, and finally these figures were compared with and expressed in terms of a pre-war base. This base of 100 represented the average monthly prices for the year July 1, 1913, to June 30, 1914.

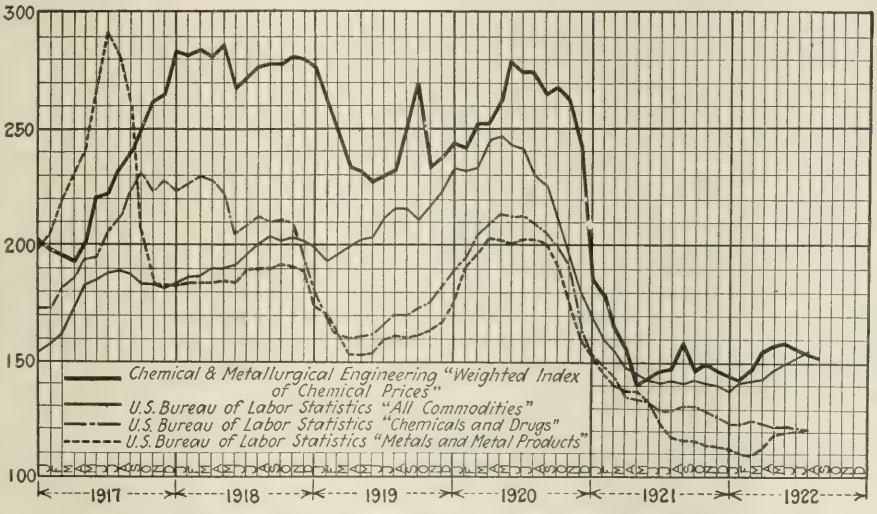

FIG. 1—THE TREND OF CHEMICAL AND METAL PRICES, 1917-1922

During the 5½ years included in this compilation the chemical market has followed an unusually interesting course. This magazine's index number rose from 191 in March, 1917, to 286 in April, 1918. Then followed a period of high prices, ending with a decline, which began at the time of the armistice and extended throughout the first 6 months of 1920. The post-war boom of 1920 had its effect about this time and prices again rose to 1918 levels. This was followed by the precipitous fall of prices during 1920, when the index number dropped from 263 in October, 1920, to 140 in May, 1921. The remainder of 1921 saw a number of minor fluctuations. During the first 5 months of the present year a consistent improvement was to be noted, but June, July and August have again shown slight declines. Prices are still considerably above the level at the beginning of the year, however, and the average for the first 8 months of 1922 is 154, as compared with 152 for 1921 and 255 for 1920.

The Trend of Production

The increasing volume of manufacture during the current year is shown in a striking manner by the statistics published monthly in the "Trend of Business Movements" section of the *Survey of Current Business*. This publication of the Department of Commerce is prepared by the cooperation of the Census Bureau and the Bureaus of Standards and Foreign and Domestic Commerce. Selected figures for certain of the more important of the chemical and allied industries are shown in Table II. From the last column of this tabulation it will be noted that with the exception of beehive coke, cottonseed and linseed oils and electrolytic copper, all of these commodities show marked increases over the corresponding periods in 1921. These range between 1.1 per cent in the case of chemical wood pulp to a gain of 112.4 per cent for the consumption of crude rubber by the tire manufacturers. The wood chemical industry,

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week 149.80
Last week 150.92

Included in this index are acetic, citric, hydrochloric, nitric, and sulphuric acids, ethyl and methyl alcohols, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash, caustic soda, copper sulphate, formaldehyde, glycerine, potassium carbonate, salt cake, soda ash, sulphur, benzene, aniline, cottonseed and linseed oils.

the only line of strictly chemical manufacture represented in this table, reports increases of 69.5 per cent in the case of calcium acetate and 34.2 per cent for wood alcohol.

Annual figures for the production, consumption and prices, 1914-1922, of the principal commodities on the chemical market are to be found in the tabulations which follow. These statistics are compiled for the most part from official sources, including the publications of the Census Bureau, U. S. Geological Survey, Bureau of Mines and Bureau of Foreign and Domestic Commerce. Production figures in the case of coal-tar products are taken from the census reports of the United States Tariff Commission, to which credit is cheerfully given for such material as is abstracted from the *Tariff Information Surveys* and the *Summary of Tariff Information.*

TABLE II—THE TREND OF CURRENT PRODUCTION IN CERTAIN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

Production of—	Feb., 1922	Mar., 1922	April, 1922	May, 1922	First 5 Months of 1921	First 5 Months of 1922	Percentage Increase or Decrease in 1922

* Shipments from Minneapolis. † Consumption by tire manuacturers.

General Chemicals

Acetic Acid

The significant development in this industry is the remarkable increase in imports, which in 1920 were more than 100 times the imports of 1914. This is due in a large measure to the development of the manufacture of synthetic acid from calcium carbide in Canada. The plant at Shawinigan Falls is reported to have a capacity of about 650 tons per month of 100 per cent acetic acid. Over 90 per cent of the imports in 1919 originated in Canada. The striking decrease in imports in 1921 was due to the accumulation of large stocks in the hands of both consumers and producers. Prices for the 28 per cent acetic acid reached a maximum of 7½@8c. per pound late in 1917, but have since fallen to 2¾ cents, as compared with a pre-war price of 1½@1⅝c.

Acetone

Before the war acetone was made exclusively from calcium acetate. War demands as a solvent and for use in the manufacture of the explosive cordite led to the development of several new processes, among them fermentation of corn, molasses and kelp. Acetone was also synthesized from calcium carbide and from the olefine gases obtained in cracking petroleum oils. Except for one producer by the fermentation method other processes have since been abandoned or are continued only on an experimental scale. It is significant to note that present prices are nearly the same as in 1914.

PRODUCTION AND IMPORTS OF ACETONE, 1914–1921

Nitric Acid

Production in the war year 1918 reached almost a million tons and in addition but slightly less than 5,000 tons was imported. Exports were also at a maximum in 1918, amounting to about 20,000 tons. Production, imports and exports have all shown marked decreases since the war.

PRODUCTION, IMPORTS AND EXPORTS OF NITRIC ACID, 1914–1921

Sulphuric Acid

None other of the strictly chemical industries attains the volume of production which is shown by sulphuric acid. The domestic output reduced to the basis of 50 deg. Bé. acid in 1918 amounted to 7,500,000 tons. Before the war exports were less than one-fifth of 1 per cent of the domestic production. In 1918, however, they amounted to 40,000 tons, valued at $1,250,000. Prices at present are considerably beneath the pre-war level. The 66 deg. acid can be purchased in the New York market for $15 per ton, as compared with $20 in 1914.

PRODUCTION, IMPORTS AND EXPORTS OF SULPHURIC ACID

Year	Producers	Production* Tons	Imports (Lb.)	Exports (Lb.)

Ammonium Sulphate

The bulk of the world's trade in ammonia is handled in the form of ammonium sulphate. Prior to the war Germany was the largest producer and annually exported from 40,000 to 70,000 tons more than she imported. England was second, exporting about three-fourths of her output. The United States ranked third, with France fourth. The tremendous increase in byproduct coke production during and since the war has put the United States on a parity with Germany as a producer of ammonium sulphate. This country has also developed a very important export trade in this commodity, as is evidenced by the fact that during the fiscal year ended June 30, 1922, exports amounted to 168,077 tons. Early in the present year prices were substantially below the 1914 quotations.

PRODUCTION, IMPORTS AND EXPORTS OF AMMONIUM SULPHATE, 1914–1922

Arsenic

The maximum annual consumption of white arsenic in the United States was in 1920, when it was estimated that approximately 15,000 tons was used. In 1921 this dropped to not more than 9,000 tons. It is difficult to estimate the consumption because of its wide variance—from 3,400 tons in 1904 to 15,000 tons in 1921. Prices since 1901 have ranged between 2¾ and 14½c per lb. Prior to 1914 most of the arsenic used in this country was imported. From 1901 to 1910 the United States produced an average of only about 975 tons, as compared with import of 4,235 tons.

PRODUCTION AND CONSUMPTION OF WHITE ARSENIC, 1914–1921

Year	Production (Short Tons)	Value	Imports (Lb.)

Barium Chloride

The domestic consumption of barium chloride before the war was supplied almost entirely by Germany, but with the cessation of imports a strong domestic industry was established. Production increased from 2,106 tons in 1915 to 4,870 tons in 1917. Imports fell from 3,000 tons in 1914 to a negligible quantity for the period of 1916 to 1919. They were resumed, however, on a considerable scale in 1920 and 1921. Barium chloride has recently become one of the more temperamental commodities on the chemical market and prices since 1914 have covered the wide range between $32 and $130 per ton.

Calcium Acetate

During the period between the federal Census of Manufactures in 1914 and 1919, the output of calcium acetate has remained practically stationary. In 1917 the War Industries Board estimated the output at 200,000,000 lb., or about 25 per cent more than the 1919 production. There has been a substantial decrease in our export trade in this commodity, which before the war accounted for at least one-third of the total production. During the fiscal year ended June 30, 1922, exports amounted to 27,606,499 lb. The price range during the period 1914 to 1922 has been between 1½ and 7c. per lb. Early in the present year prices had fallen to 1¾c.

PRODUCTION AND EXPORTS OF CALCIUM ACETATE, 1914–1922

Bleaching Powder

Production of bleaching powder fell from 310,380,000 lb. in 1914 to 177,140,000 in 1919. This can be attributed largely to the increasing competition from liquid chlorine. Imports, which in 1914 amounted to almost 50,000,000 lb., fell to less than 1,000 lb. during 1918. There has been some resumption of imports, but even in 1921 when 12,440,906 lb. was received, this was still considerably less than our export trade in this commodity. During 1920 48,826,348 lb. was exported, principally to the Latin-American countries. Present prices are approximately at pre-war levels.

PRODUCTION, IMPORTS AND EXPORTS OF BLEACHING POWDER, 1914–1922

Formaldehyde

Production of formaldehyde more than doubled during the 5-year period 1914 to 1919. In the former year three producers reported an output of 8,426,247 lb., while in 1919 six establishments produced 19,663,753 lb. This increase is probably due to the remarkable industrial development in the manufacture of synthetic resinlike products which are made by the condensation of formaldehyde with hexamethylenetetramine, phenol, or cresol. Imports prior to the war were practically negligible, but in 1920 amounted to 428,444 lb. It is significant to note that recent price reductions have brought the general level down to that which existed prior to 1914, although during the boom of 1920 prices were more than five times present quotations.

PRODUCTION AND IMPORTS OF FORMALDEHYDE, 1914–1921

Copper Sulphate

Blue vitriol, produced largely as a byproduct in copper refining, reached a maximum output in 1916, when 55,622,345 lb. was produced by the refineries. During both 1916 and 1917 the United States enjoyed an unprecedented export trade principally to the countries of southern Europe, where copper sulphate is used as an insecticide in grape culture. Late last year prices were at practically pre-war level, but increases since that time have brought quotations up to about 6¾c. per lb.

Glycerine

The market production of glycerine in 1919 was reported by the Census as follows: Refined glycerine, 64,342,800 lb., valued at $20,724,000, and crude glycerine, 21,304,300 lb., valued at $2,961,600. Pre-war imports of crude glycerine ranged between 13,000,000 and 14,000,000 lb. annually, 50 per cent coming from England and France. Since the war the imports of crude glycerine have fallen off markedly; in 1918 but 1,445,000 lb. was received. The three years 1916, 1917, and 1918 were the boom years for glycerine prices, which in 1918 reached 64c. per lb. as compared with 14¾c. at present.

Potassium Carbonate

Imports of crude carbonate of potash formerly averaged about 20,000,000 lb., coming chiefly from Germany. In 1916 they fell to a minimum of 444,241 lb. During the war a small quantity of crude carbonate was produced in this country from wood ashes; the 1917 output was 2,070,000 lb. In 1919 production was up to 48,664,478 lb., valued at $2,299,926. The carbonate is one of the cheapest of the crude potash salts and prior to the war sold for 3c. per lb. During the boom of 1916 prices reached as high as 85c. per lb. for the small quantities that were obtainable. Present quotations are practically at pre-war level.

Potassium Ferrocyanide

In 1914 yellow prussiate of potash was produced in an amount which represented approximately half of the total domestic consumption. In 1918, however, production by three firms amounted to only about a half million pounds, and imports had fallen to 135,000 lb. The reason for this striking decrease both in the production and in the consumption is the substitution of sodium ferrocyanide instead of the potash salt. During the current year yellow prussiate of potash has often been very difficult to obtain, and prices have advanced from 26c. to 33c. per lb. during the last 6 months. The highest war-time price was $1.80, quoted in April, 1916. At that time the red prussiate of potash (potassium ferricyanide) was practically $3 per lb.

Potassium Hydroxide

There was but one domestic manufacturer of caustic potash prior to the war, and more than half of the domestic consumption was imported from Germany. According to a statement made before the Committee of Ways and Means in 1921, the 1914 output of this firm was reported as 6,504,000 lb. The output in 1919, according to the Census, was 8,358,834 lb. Prices as high as $1 per lb. were noted for the 88 to 92 per cent caustic potash during the second quarter of 1916. At present heavy quotations from Germany have caused prices to sag so that the present scale is around 5½@6c. per lb.

Soda Ash

Next to sulphuric acid, soda ash is probably the most important chemical as regards the volume of production. In 1918 the output amounted to 1,390,628 lb., valued at $35,685,520. Imports are an inconsequential factor and have generally amounted to less than 1 per cent of the domestic production. Since the war the United States has developed an important export trade in soda ash. The record year to date is 1918, when 238,434,992 lb. was exported, principally to Japan, Canada, Sweden and the Netherlands. There has been considerable reduction in the prices that obtained during 1920, but present quotations are much higher than the 1914 and 1915 figures. At that time prices were around 60c. per 100 lb., as compared with $1.75 now.

Sodium Bichromate

Sodium bichromate and sodium chromate are reported together in both production and import figures. The combined output of these salts in 1914 was 11,824 tons, and in 1918 this had increased to 28,334 tons. The value in the latter year was $9,868,118. Prices in 1914 were fairly stable at 4¾c. for the bichromate salt. After reaching a peak of 36c. per lb. in 1920, prices have declined until at the present time the salt is obtainable at 7½c. per lb.

Glaubers Salt

Glaubers salt is obtained as a by-product in the manufacture of hydrochloric acid and its production is, therefore, largely dependent upon that commodity. In 1914, 34,537 tons was produced with a value of $427,808. In 1918 a maximum output of 50,715 tons was reported. Imports of glaubers salt have never been large and are negligible compared with domestic production. Prior to the war, this salt was quoted at approximately 60c. per 100 lb., but during the 1920 prices as high as $2.50 were heard. At present prices are in the neighborhood of 90c. to $1 per 100 lb.

Sodium Hydroxide

Caustic soda is second in importance to soda ash among the alkalis. During 1917 and 1918 large quantities of caustic soda were used in the production of synthetic phenol, which in turn was used in the manufacture of the explosive picric acid. The 1918 production was over a half million tons, valued at approximately $32,000,000. In 1917 eight firms used the soda ash method of producing caustic soda, and twenty-eight companies produced caustic soda electrolytically. About 28 per cent of the output in 1917 and 1918 was produced by the latter method. Imports in 1921, the largest on record, amounted to only about 700 tons. Exports, on the other hand, reached a maximum in 1920 of 112,000 tons. Japan, Italy, South America and Canada are the principal customers for American caustic.

Sodium Ferrocyanide

Sodium ferrocyanide or yellow prussiate of soda is obtained as a by-product in the purification of coal gas. It can also be prepared from sodium cyanide. Production in 1917 was 4,173 short tons, valued at $2,577,667. Since 1917 there has been a consistent increase in the import of yellow prussiate of soda. In 1921 approximately 1,250 tons was imported. This commodity has shown a wide range of prices in recent years. From a pre-war price of less than 10c. per lb. quotations rose until in 1916 as much as $1.25 per lb. was being obtained. Since that time the general trend of the market has been downward, although after reaching a minimum of 12½c. in July, 1921, there was an upward reaction to over 20c. per lb. during 1922.

Sulphur

The primary problem of the sulphur industry is to enlarge its market. The potential production of the domestic mines is in the neighborhood of 2½ million tons, whereas the actual production at present is not over one-half of that. Sulphur is in direct competition with pyrites in the acid-making industry and over one-half of the one million tons of sulphur sold in the United States in 1920 was used in the manufacture of sulphuric acid. A consideration of the following tables will show that during the last 10 years production has been considerably in excess of domestic shipments. There is at present an accumulation of approximately two million tons of sulphur, mined and ready for the market. Except for a short period during 1918 and 1919 the price of sulphur has been remarkably stable. At present quotations of $18 per ton f.o.b. New York are considerably under the pre-war figures.

PRODUCTION AND CONSUMPTION OF SULPHUR, 1909–1920

Coal-Tar Products

Aniline Oil

Aniline oil occupies the same position of relative importance among the coal-tar intermediates as does sulphuric acid among the general chemicals. It is used in the production of a wide range of important dyestuffs. In 1920 the output of this intermediate alone amounted to 39,234,186 lb., valued at almost $11,000,000. The marked decrease that occurred in dye production during 1921 is well evidenced by the fact that the production of aniline oil shows a decrease of 86 per cent from that of 1920. The production of aniline salts (aniline hydrochloride and aniline sulphate) fell from 2,024,956 lb. in 1920 to 366,533 lb. in 1921. Imports of aniline oil have been of practically no significance since 1914. Prices have followed an unusually wide range, from 10c. per lb. in 1914 to as much as $1.10 per lb. during the shortage of 1915 and 1916. Present prices are around 15c. per lb.

Benzene

A striking increase in production has been noted in the case of benzene, the most important of the so-called coal-tar crudes. In 1914 the production of crude light oil was 8,464,274 gal., equivalent to a production of about 4½ million gallons of benzene. In 1918 44,804,900 gal. of benzene was produced in this country. Much of this, however, was used as raw material for explosives. In 1920 the Geological Survey reports on the production as follows: Crude, 8,747,572 gal., refined, 16,977,556 gal., and motor fuel 57,645,462 gal. The latter varies in benzene content from 50 to 100 per cent. It is evident from these figures that the productive capacity for benzene is far in excess of that required for the manufacture of dyes or other chemical products. Directly following the armistice prices of benzene dropped to less than pre-war, but since that time have increased until at the present writing benzene is quoted at approximately 29c. per gal.

PRODUCTION OF BENZENE, 1916-1921

Beta Naphthol

Technical beta naphthol is the most important of the napthalene derivatives. The output in 1921 was 2,959,049 lb.—a 75 per cent decrease from that of the previous year. The maximum production in 1920 corresponds with the period of greatest output for the industries using para reds and other important colors in which this intermediate is used. The price of technical beta naphthol prior to the war was usually less than 10c. per lb. Prices were over ten times this figure in 1915 and 1916, but with the increasing production in 1918, 1919 and 1920 prices have shown a rather consistent decline and at present the quotations are in the neighborhood of 23c. per lb.

Naphthalene

It is difficult to give reliable figures for the production of naphthalene, due to the fact that it is produced from several different sources and in at least two grades. The figures in the accompanying table are those reported to the United States Tariff Commission as the production of refined naphthalene (solidifying at 79 deg. C. or above). The 1921 output of 13,183,142 lb. is a decrease of 55 per cent from that of 1920. It should be pointed out, however, that these figures do not include the output of naphthalene at coke ovens, data for which are usually collected by the Geological Survey. An idea of the extent of the production of crude naphthalene in the United States during 1918 may be gained from the following figures reported by the Survey: From tar distillers, 40,138,092 lb., valued at $1,281,440; from coke ovens, 10,614,799 lb., valued at $292,868; from gas houses, etc., 428,088 lb., valued at $11,558. This is a total of 51,180,979 lb., valued at $1,585,866. Imports during the 1914 fiscal year were 3,880,108 lb., valued at $70,428. Since the passage of the tariff act of 1916, imports of refined naphthalene have been less than 1 per cent of the domestic production.

PRODUCTION OF NAPHTHALENE, REFINED FLAKE, 1917–1921

Year	Number of Producers	Production (Lb.)	Value	Value per Lb.
1917	12	35,342,911	$2,334,302	$0.07

Paranitraniline

The output of this important intermediate used in the manufacture of para reds and various color lakes reached a maximum in 1920 of 2,138,492 lb., valued at $2,500,000. The 1921 output showed a decrease of 61 per cent as compared with the previous year. The pre-war price of paranitraniline was 16c. per lb., but for 6 years following the cutting off of German imports prices were well over $1 per lb. During 1921, however, there was a gradual and consistent lowering of prices.

PRODUCTION OF PARANITRANILINE, 1917–1921

Year	Number of Producers	Production (Lb.)	Value	Value per Lb.
1917	9	1,724,008	$1,952,229	$1.13

Phenol

Phenol is another commodity which offers difficulties to the statistician, largely because of grades and varying sources of production. The years 1917 and 1918 showed enormous outputs of phenol, which, of course, was used almost entirely in the production of explosives. Much of the 106,794,277 lb. produced in 1918 came from synthetic phenol plants operating under government contracts. With the signing of the armistice, large stocks of government phenol were placed on the market. Approximately 25,000,000 lb., or nearly three times the normal annual consumption, was offered for sale. Naturally, this had a most depressing effect both on production and marketing of this article. The 1919 output was only 1,500,000 lb., valued at about 10c. per lb. There were but two producers during 1920, and their production could not be published. In 1921, the output had fallen further to less than a third of a million pounds.

PRODUCTION OF PHENOL, U.S.P. AND TECHNICAL, 1917–1921

Year	Number of Producers	Production (Lb.)	Value	Value per Lb.

The Travelers Returned

ARRIVING within 10 days of each other, Dr. ELLWOOD HENDRICK and J. S. NEGRU of *Chem. & Met.'s* editorial staff recently returned from extended sojourns in England and on the Continent respectively. Dr. HENDRICK spent 2 months among the chemists of Great Britain, while Mr. NEGRU traveled for more than 6 months throughout the length and breadth of Belgium, France, Italy, Switzerland and Germany. That they have returned with fresh and original points of view on the chemical industry of those countries is the natural consequence of their interviews with men of high and low degree. They had unusual opportunities for observation and will be able to interpret foreign conditions in the language of our readers. Mr. NEGRU'S contributions will begin in our next number with a summary of his views on the cause of the financial breakdown in Germany. Considering the variety of causes that have been assigned for this condition it is interesting to note that Mr. NEGRU feels that Germany has brought disaster upon herself through an unsuccessful effort to wage an economic war on the rest of the world.

In this issue Dr. HENDRICK portrays in intimate detail the peculiar condition of the dye industry in England. There is a point in the history of the British corporation that reminds us of one of the cardinal errors made in the administration of the National Analine & Chemical Co. before it was incorporated into the Allied Chemical & Dye Corporation. Business is an art, and those responsible for the administration of business affairs must make things go. There is no excuse for failure to get along with the men who are needed. Again, business is like the institution of marriage: nobody knows how the parties to the contract are going to get along together, but they *must* get along or make a failure of it. In Buffalo there were the SCHOELKOPFFS, J. F. 2nd and 3rd, who were competent to make dyes and who knew the business. They were bought out because they couldn't agree with men who were lacking in the very knowledge which they enjoyed. They had had unique experience. The art of business required that these two singularly equipped men should have been kept in the organization so that it might profit by their help and their understanding. Conditions in the dye industry in the United States today would have been far better if they had remained active.

In England there was surely nobody having the wide experience in making dyes enjoyed by Dr. HERBERT LEVENSTEIN and quite aside from whatever his administrative ability may be or his capacity to get along with Sir JOSEPH TURNER, he should have been retained as part of the organization. In America we started well and then piffled out. In England they started badly, grew better, but lost a leading trick in the process.

But the most striking feature of the foreign situation is the part that Germany undoubtedly desires and is planning to play in the international control of dye manufacture. It is doubtful if Great Britain will succumb to the German wiles as France and Italy have—at least not on terms that will emasculate the industry and leave Great Britain helpless in time of national emergency. But the situation holds its lesson for those in whose hands rests the welfare of an American dye industry. With France and Italy already controlled and with the possibility of an industrial alliance with Great Britain, the German I.G. may well snap its fingers at the efforts to build a dye industry in this country. If ever conclusive proof were needed of the necessity of tariff protection until technical knowledge and business skill can work out our own salvation, it is to be found in the story disclosed in Dr. HENDRICK'S article. The helplessness of France and Italy will be our portion unless our law-makers get an intelligent comprehension of the importance of the chemical industry to our national welfare.

A Hopeful Prospect for Leadership in the House

FREQUENTLY the chemical industries have looked despairingly toward Washington for an intelligent, if not sympathetic, understanding of their problems. The leaders in the national legislature have often understood other industries, have been sympathetic with and even partial to them, but the chemical industries have enjoyed few friends at court. This is distinctly to be deplored. The chemical industries do not need partiality or even sympathy, but they do need an intelligent understanding.

It is, therefore, with a distinct feeling of hope that the news is received that NICHOLAS LONGWORTH probably will become Republican leader in the House of Representatives on the retirement of Mr. MONDELL next March. LONGWORTH has served his constituency and the country well and ably. In his tenure of office he has won for himself a high regard, not by reason of any spectacular brilliancy but because of his balance, his sane and informed opinion on a great many subjects. His rivals for the post of leader of the party in the House have all suffered severe blows in their own districts in the primaries, and LONGWORTH stands in line for the well-deserved honor.

Chemical industry has reason to rejoice that LONGWORTH will assume a commanding position, for he has held an enlightened opinion on chemical legislation. This does not imply by any means that he has been partial or in any way played the chemical industry as a favorite, but he has understood its problems, and that is the thing most to be desired by any industry as far as Congress is concerned.

Electrochemists Go to Canada

IN OUR news columns will be found the detailed program of the forthcoming Montreal meeting of the American Electrochemical Society, Sept. 21 to 23. It is seldom that the usually excellent programs of this lively organization have afforded so good a prospect of technical discussion and social diversion as the one for the Canadian meeting this month. The sessions on industrial heating under the direction of BRADLEY STOUGHTON of the electrothermic division give promise of unusual interest. Electrodeposition will also receive special attention at one session. The industrial feature of the meeting will be a special excursion to Shawinigan Falls for the inspection of industrial plants at that great Canadian center of hydro-electric power and electrochemistry. Social features will not be lacking. Older members particularly are likely to grow reminiscent over the note that "an old-fashioned smoker" will be given by the local committee, while the novice can be assured that he will be entertained right royally if he attends. The excellence of all the arrangements insures a large attendance and an unusually profitable meeting.

Living Wage And Performance

THE matter of a "living wage" continues to be pressed upon the Railroad Labor Board. In the hearings preceding the decision of the shopmen's case B. M. JEWELL insisted that a living wage was $2,637 a year. Recently the maintenance-of-way men formally demanded that the board recognize the "living wage," claiming that the transportation act requires that this be considered, but the board had ruled otherwise.

The transportation act prescribes as the second of the seven points that are to govern the board: "The relation between wages and the cost of living." Taking this statement by itself, the natural interpretation is that wages are to fluctuate according to the cost of living. In analyses accompanying its decision the board has made comparisons between prescribed wages and those in force in December, 1917, the month before the government took over the railroads; also comparisons between the existing cost of living and that in December, 1917. Confirmation of this view of the intention of Congress is found in the seventh point: "Inequalities of increases in wages or of treatment, the result of previous wage orders or adjustments." Thus even the "inequalities" are limited to those that result from recent acts. Congress plainly assumed that railroad wages in general had been about right, and the chief duty of the Labor Board was to correct divergences.

From the viewpoint of the general economic good and the peace and contentment of the people at large it is to be regretted that the Railroad Labor Board, with the great prestige its decisions must command, is not forced to go into this subject of the "living wage." There are some who consider the whole subject entirely nebulous, because the unions have made the living wage, by inventory, so many shredded wheat biscuit, so many pairs of children's shoes, etc., and each item is open to discussion. Others consider it out of the question, on the ground that "it can't be done"—i.e., can't be paid.

The latter objection brings out the very point that should compel attention to the subject, rather than abandonment of it. The argument is that the total income—i.e., the total production, including the rendering of service with the production of commodities—is not sufficient to give each worker what the alleged "living wage" would buy at present prices. What mor sensible thing could be done, then, than set down wha is the supply, and allocate it to the workers?

This would furnish the true basis of the "livin wage," not what a man ought to have according to hi notion of an alleged "American standard," but accord ing to what he contributes to the total. Suppose it b found that the total income is $60,000,000,000 a yea that 25 per cent should properly go for the use of capita and the services of those who manage and invest an 75 per cent to those who work and that there ar 40,000,000 workers. The figures taken are near enoug the fact to be suggestive. Then rate the workers on scale with 100 as the base or average. Many would b worth 60, 70, 80, 90, 100, 110 and 120. Some woul run up to 150, 200 and 250 and a few would run sti higher. The 40,000,000 people would receive a tota of $45,000,000,000, an average of $1,125 per capita Some would receive 90 per cent of this, some 110 pe cent, and so on.

Objection may be made that anything of this sor would raise a terrific clamor. The 90 per cent me would claim the 110 per cent men didn't do anythin worth while and would be overpaid at 80, and so on Precisely. That is just what is needed. The psycho logical influence would be of tremendous value. Th trouble today is the public doesn't realize that it pay the coal miner, the bricklayer and the other workers It thinks the wicked employer merely has to dig dow into his pocketbook for the money.

Celebration of Fire Prevention Week

FROM Oct. 2 to 9, Fire Prevention Week will b celebrated throughout the United States and Canada This campaign will be given all the publicity possibl through the newspapers, and will be the subject o meetings, parades, moving picture programs and a special campaign for school children.

With the coal situation in mind and most of us wit empty bins, it may be more difficult than usual to con centrate on prevention of fire. But a short contempla tion of the present fire situation will amply convinc the most worried householder that this campaign wil repay all the attention he is able to give it. The annual losses from fires—most of which are preventable—have averaged 15,000 lives and $500,000,000 in property for the past few years. And the yearly figures show these losses to be on the increase.

Fire prevention is an item of daily care to all those in responsible charge of industrial plants. There is no need to remind them that every week is fire prevention week so far as they are concerned. Their chief problem is to sell the idea to all those, employees and others, who may help in this work or who may be the unthinking causes of these losses.

It is in selling this idea that the value of Fire Prevention Week lies for the plant executive. We all remember, from Liberty Loan and War Chest drives, that one of the great lessons of the war was the value of the intensive campaign—the full effort concentrated over a short period—the campaign which drives the idea home and clinches it. By means of posters, motion pictures and mass meetings the need for the utmost care in fire prevention can be made clear to every employee.

We hope everyone responsible will see his way clear this year to putting in the energy, thought and money which are necessary to make Fire Prevention Week really fruitful. Such expenditure will be fully repaid.

Chromium Steels And Alloys

ONE of the first lessons an editor learns is to refrain from superlatives—leave them to his advertisers—so we refrain from calling chromium a "master metal." Perhaps it has been so dubbed. Iron is truly worthy of the title. Other metals doubtless have been given it as well, particularly tungsten, which during the war was hailed as one of the "keys" to victory and economic independence. Tin was another "key," and nations were hard put to discover how they could insure an adequate supply, despite war, embargoes and U-boats.

Tungsten, as a requisite for high-speed steels and a relatively scarce metal at that, doubtless warranted all the attention it got during those busy days of enormous munition production. But its more common partner chromium is no less an indispensable ingredient of high-speed steel—indeed, it is the combination of the two which gives those unique characteristics of modern tools: hardening on slow cooling, gain in hardness on tempering and retention of hardness at red heat.

Nor is chromium's usefulness limited to high speed and air hardening (Mushet) tool steels. Nickel-chromium steels are without doubt the most widely used type of alloy steels; the tonnage comprises a very large fraction of the whole. Inasmuch as they ordinarily contain more than twice as much nickel as chromium, it might be thought that the latter was of distinctly secondary importance. But this is by no means true.

Plain nickel steels are tough and ductile, whereas the addition of chromium hardens the alloy without materially impairing those other advantages. The result is a very strong, tough alloy, which possesses high endurance under repeated loads, and it is therefore widely used for high-speed gas engines and automobiles. No less than fifteen separate analyses have been standardized by the Society of Automotive Engineers, containing some most excellent grades for case-hardening. Carburized nickel-chromium steels give pieces of very hard surface, not nearly so brittle and likely to flake off as the plain carbon steels. Furthermore, the reactions induced in nickel-chromium steels by heat-treatment go forward at such a modest speed that even the interior of fairly large masses of metal can be treated and cooled at a rate which will develop the correct physical properties to the very center of the piece. In other words, mass has singularly little effect on heat-treatment, and this explains why nickel-chromium steels are favorites among armor makers.

Despite the temptation, it would carry us somewhat far afield to cite the properties of the more familiar steels, low, medium and high in alloy content. Suffice it to say that oil-quenching gives them very high strength, with fair ductility but relatively low impact values. (An analysis recommended by the Midvale Steel Co., for structural purposes, containing 0.40 per cent carbon, 0.75 per cent chromium and 3 per cent nickel, may have an elastic limit of 245,000 lb. per sq.in.—near the peak for commercial heat-treated steel.) Tempering such steels must be done with circumspection to avoid embrittlement, but when properly accomplished is able to raise the ductility and impact resistance enormously, although not without a considerable sacrifice in strength.

But plain chromium steels have themselves a unique place in the field of alloys. Chromium, either alone or in combination with iron, forms a very stable carbide, diffusing itself throughout the metal, inducing a very fine grain and corresponding great toughness because of its reluctance to accumulate into sizable masses. The carbide is very hard, and causes the quenched steels to be very hard. Furthermore, the chromium remaining after all the carbon is satisfied enters into solution in the iron and confers great corrosion resistance to the base metal. All these properties produce metal tough and hard, extremely resistant to wear and rusting, suitable for well bits, cold chisels and other shock tools, files and knives, ball bearings, rollers, crusher liners, safes, burglar-proof metal and armor-piercing projectiles.

As the chromium goes above 10 per cent, the region of "stainless steels" is entered. Most excellent and deservedly popular cutlery contains 13 to 15 per cent chromium with about 0.4 per cent carbon. In low-carbon steels, less chromium is needed to retain a silvery finish; furthermore it is cheaper and more easily worked into sheets and forged into shapes. Consequently "stainless iron" is appearing on the market and is said to be winning favor rapidly in England for metal trim of all sorts. But the older "stainless steel" analyses are by no means confined to cutlery—they can assume a wide variety of physical properties by appropriate heat-treatment, and are logical contenders for many machine elements and engineering purposes, from turbine blades to mine cables. Even higher alloys of iron-carbon-chromium have unique properties. Containing 20 per cent and more of chromium, they were developed for their remarkable resistance to oxidation, but have been discovered to possess great tensile strength, even as high as 700 deg. C. Furthermore, the high-carbon alloys resemble white cast iron in hardness and resistance to wear, yet are as tough as a good steel.

This account of a remarkable metal would not be complete without mentioning the importance of certain nonferrous chromium alloys. Much might be said of alloys of nickel and chromium. They have made electrical heating a commercial possibility. Wires and ribbons of it are universally used in laundry irons, hot plates and toasters, baking ovens and cookers of hundreds of varieties, for bread making, enameling and all sorts of heat-treatment. (In addition to these electrical resistors, several cheaper iron-bearing alloys for resisting high temperature contain more or less chromium as a prime essential.) Another alloy, stellite, is used for machine tools and for surgical instruments. Stellite is essentially an alloy of chromium and cobalt, and contains some tungsten.

However, all these advantages are not to be had without serious effort and expense. Chromium metal and alloys low in carbon, silicon and aluminum are difficult to make, and at present are quite expensive despite the relative abundance of the ores. Chromium oxidizes scarcely at all below its melting point, but when molten apparently oxidizes very readily. Most chromium-bearing alloys, unfortunately enough, are extremely sensitive to oxide inclusions. In steel making, for instance, if there is the least carelessness in the manufacture, if the charge is of inferior scrap or is badly oxidized during melting, if the refining stages be slighted in the least, if the casting and rolling are done in a slipshod fashion, a whole train of troubles and disappointments is in store. Surface cracks, from hairlines to roaks, will abound, flaky fractures will appear, soft spots will follow case-hardening, and a ground and polished surface of a roller or ball will develop markings like an alligator skin.

Like most good things, it doesn't come easy!

Readers' Views and Comments

Dr. Hendrick's English Tour

To the Editor of Chemical & Metallurgical Engineering

SIR:—The visit to England of Dr. Ellwood Hendrick, consulting editor of *Chemical & Metallurgical Engineering*, terminated on Saturday, Aug. 19, when he sailed on his return to the United States. His visit covered just exactly 2 months, and it enabled Dr. Hendrick to see a great deal of the leading personalities in British chemical industry and to inform himself at first hand concerning the special problems now engaging their attention. I saw him a few days after his arrival and a few days before his return. He looked at least 10 years younger for his holiday, was full of praise for the hearty hospitality showered upon him, and more deeply impressed than ever with the essential unity of the two great English-speaking nations. What we shall remember most is the spacious social atmosphere he carries about with him and the large-hearted human qualities which have made him welcome everywhere. He has become a sort of institution at the Chemical Industry Club, London, and at the annual meeting of the Society of Chemical Industry in Glasgow he was one of the most picturesque and popular figures. In fact, he seems during the past 2 months to have been present at every gathering worth attending, and everywhere he has been accepted as a true friend. His big, genial figure, his infectious smile, his good humor, good fellowship and real largeness and kindness of heart will long be remembered by all who met him during his stay; and on his side, one fancies he will carry back to the States equally pleasant memories of the friends and colleagues he dined, and smoked, and chatted with —in public and in private—during his 2 months in the old country.

FREDERICK E. HAMER,
London, England. Editor, *Chemical Age*.

Black Fractures in Carbon Tool Steels

To the Editor of Chemical & Metallurgical Engineering

SIR:—I was much interested in the article on "Black Fractures," particularly so as this phenomenon has been fairly well understood in the tool steel industry for a number of years. It is commonly regarded as a precipitation of graphitic carbon from cementite. This precipitation takes place on prolonged annealing in the region of and immediately below the Ar_1 point. A reference on this subject which has been in print for considerable time is on page 416 of Dr. C. M. Johnson's book on "Rapid Methods for the Chemical Analysis of Special Steels." At the moment I do not recall a paper which gives complete quantitative information upon this phenomenon. Such an account should be written.

J. V. EMMONS,
Cleveland, Ohio. Metallurgist, Cleveland Twist Drill Co.

To the Editor of Chemical & Metallurgical Engineering

SIR:—It is a little surprising that Mr. Green does not recognize this peculiar appearance described in his article on "Black Fractures" in your journal for Aug 9, 1922, p. 265, as due to the existence of temper carbon. The exact conditions under which high-carbon steel sometimes deposits free carbon are not known, but in general we do know that it is the result of bad mill practice. Excessive temperatures in the first cogging operations and low temperatures below the recalescence point in the annealing represent the two conditions which most frequently account for temper carbon.

It is possible for temper carbon to exist up to a considerable amount without showing "black fractures." It is also recognized by experienced tool steel men that steel containing temper carbon can be hardened, but the result in the hardened steel shows a characteristic dry and stony fracture and is very weak in strength. It appears that about 0.90 per cent carbon dissolves readily above the Ac_1 temperature, and this is sufficient to produce hardening. The balance of the free carbon goes into solution with greater difficulty in the heated steel unless the temperature be carried too high for good hardening results. The excess carbon remaining in its graphitic condition accounts for the weak dry structure. The cementite usually passes into globular form just prior to decomposing into iron and carbon when conditions for such decomposition are right.

JOHN A. MATHEWS,
New York City. President, Crucible Steel Co. of America.

To the Editor of Chemical & Metallurgical Engineering

SIR:—The trouble described by Mr. Green as "Black Fractures" has been well known for many years, in connection with the annealing of crucible steel, or any steel of relatively high silicon content, and not containing appreciable amounts of non-ferrous elements that deter, or entirely prevent, the formation of graphitic carbon under favorable conditions of temperature.

It is the property of iron that it cannot retain carbon in the combined state when silicon is in excess of about 0.10 per cent and the carbon is much in excess of 0.90 per cent, if the steel is held for *prolonged* periods at or below 700 deg. C. As H. M. Howe stated in his "Metallography of Iron and Steel," p. 215, graphite is the stable form of carbon and cementite is only a metastable form always striving to change over into graphite by the reaction:

$$Fe_3C = 3Fe + \text{Graphite}.$$

Silicon is the greatest promoter of graphite of any non-ferrous element found to any extent in iron and steel. Mr. Green mentions in his article a steel containing 0.25 per cent silicon. This is quite sufficient to promote readily the "black heart" fracture in a steel where the carbon is as high as 1.15 per cent. If the silicon is much under 0.10, it is quite difficult, if not entirely impossible, to obtain black fracture in the higher carbons—1.15 to 1.35 per cent—by prolonged anneals at the favorable range of 660 to 700 deg. C.

For example, the only way the writer was able to get a precipitation of graphite in "washed metal" which contains about 3 per cent carbon and is very low, usually under 0.05 per cent, silicon, was to heat it for several hours at about 1,050 deg. C. So great is the influence of silicon that Charpy and Thenard were able to graphitize completely all the carbon in steels from as low as 0.40 to 0.14 per cent carbon by raising the silicon content to 4 per cent. In this case the graphitization

was complete in 3 hours at 800 deg. C. With 2.20 per cent silicon, no graphite formed.

Assuming the absence of modifying elements, hypo-eutectoid steels generate cementite at or below 700 deg. C. and hyper-eutectoid steels at increasingly higher temperatures as the carbon content rises, so that for the 3 per cent carbon "washed metal," a temperature just under its melting point is the most favorable.

The presence of two or three-tenths of 1 per cent of chromium is a great deterrent of graphite formation. Also manganese is said to act in the same way. This is due to the formation of much more stable carbides of chromium and manganese. It is quite likely that tungsten and molybdenum act as deterrents also. As spheroidizing anneals and long heating periods tend to promote graphite formation, the heating periods should be made as brief as possible. Repeated reheatings at lower temperatures also tend to produce black steel.

The best use for steel containing considerable graphite, as far as good tool steel is concerned, is to drop it quietly on the scrap pile for remelting.

C. MORRIS JOHNSON,
Research Department,
Crucible Steel Co. of America.
Pittsburgh, Pa.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I must admit to Dr. Mathews that I did not recognize the existence of "temper carbon," but did acknowledge that poor or bad mill practice was at times responsible for the production of black fractures. I have found that the steel when hardened has a dry and stony fracture as stated in his letter, and regret that I did not include that observation in my article.

Mr. Johnson's letter I find particularly interesting, and have found in my experience with black fractures that I have verified his statements regarding the rôle of silicon in the production of black fractures. I also agree with him that the scrapping of the material is quite necessary.

Although I never entertained the thought that I was writing anything new when I wrote the article for publication, I am very much interested in the amount of comment it has aroused. It may ultimately lead to the publication of a very conclusive article on this subject.

Chemists in Public Life? Why?

To the Editor of Chemical & Metallurgical Engineering

SIR:—After reading S. L. Redman's communication in "Chemists in Public Life" in your issue of Aug. 16 I left my workbench and sat down in the "office" of the laboratory to reflect. Just why do chemists want to get into public life anyway?

Chemists are chemists because they possess an interest in nature. For my part I look upon my 22 years in chemical laboratories about the same way an art student does. I don't want to be in public life; I leave that to lawyers and professional politicians. Lots of us don't want to be executives either; we just want to be left alone. I have been an executive. I became one once because my friends said I ought to be one and that I would obtain a big salary. I was successful. I managed blast furnaces for 3 years, to the entire satisfaction of the owners.

Every time I went to the laboratory and saw my chemist working on the analysis of pig iron, slag or iron ores, I said to myself, I wish I was back in the laboratory again, it is much more interesting than simply being an executive. My work as an executive consisted in trying to see how few men I could employ to man the blast furnace, the smallest pay I could offer to fill vacancies, the lowest coke consumption I could use to make merchantable pig iron, and to doctor the troubles of men, plant and process. I tried for 3 years to feel satisfied as an executive. I found the work uninspiring, tiresome and boring. I resigned to go back to the laboratory. I have been back 14 years and feel glad that these 14 years have not been wasted by simply "being an executive."

RANDOLPH BOLLING.
Norfolk, Va.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read the letter of S. L. Redman in your Aug. 16 issue with much interest. I heartily agree with Dr. Redman that the laboratory inclination of the product of colleges and universities is traceable directly to the ideas that are instilled at these institutions. But in spite of this training there are some who never regard a laboratory position as other than an introduction to other activities.

There is a class of organizations that should be as severely condemned for fostering this conception of the field open to the chemist. I have heard executives, on receiving applications from men of chemical training, state that their organization did not have any openings that would be of interest to a chemist *because they did not maintain a laboratory.* These managers regard a chemist as useful merely for analytical work and entirely incapable of responsibilities outside of the laboratory. Unquestionably the chemist, individually and collectively, is responsible for this attitude. Many chemists as well as others are willing to accept the order of things as they find them.

The employer who has never retained a chemist in another capacity is loath to try the experiment, usually contending that because a man has never before performed a given operation it is beyond the realm of possibility that he will be able to succeed. When the institutions of learning stop teaching the chemist that his field of endeavor is the laboratory, and the manufacturer, sales organizer, etc., stop conceiving of chemists in terms of laboratories, analyses and expenditures and consider him as a possible asset, economist and producer, then the bulk of our graduates will not be seeking laboratory jobs and the employers will have to find another alibi for "we do not have a laboratory."

A. E. MAZE.

New Source of Creatin

To the Editor of Chemical & Metallurgical Engineering

SIR:—So much research is apparently being carried out by biochemists and others upon creatin and related compounds that it seems desirable to note that a new source of this substance has been discovered which will make it available in much larger quantities than heretofore. Pure creatin will soon be purchasable through regular supply houses at a price which will be a fraction of 1 per cent of the present price; or the writer will be glad to distribute reasonable quantities direct, for research purposes.

It is hoped that this new source of creatin may serve to stimulate research in this field, since the quantities now available will permit research by the synthetic organic chemist as well as by the biological chemist.

The writer will be glad to give further details to anyone interested.

GRAHAM EDGAR,
Professor of Chemistry.
University of Virginia,
Charlottesburg, Va.

Canadian Meeting American Ceramic Society

THROUGHOUT the week of Aug. 14 Canadian ceramists were hosts to visiting members of the American Ceramic Society on one of the most enjoyable summer excursion meetings on record. Exceptional opportunities for recreation, instruction and good fellowship were afforded by a trip which covered points of ceramic and historic interest from Montreal to Hamilton. The success of the meeting was due in no small measure to the local committee at each point, who arranged programs of plant visits and entertainment and in many other ways looked after the comfort of their visitors. The inconveniences of traveling were minimized through the courtesy of the Canadian Pacific Railway officials, who furnished special parlor cars and sleepers. And no expression of gratitude could be complete without mention of the untiring general secretary, Ross C. Purdy. He alone knows the trials encountered in attempting to keep the little band of explorers intact, particularly when it became necessary to leave behind the shores of Quebec.

As is customary at summer meetings, no technical sessions were held, but three evenings were devoted to Section Q in the most approved pre-Volstead style.

Boat Trip to Montreal

About fifty members boarded the steamer Kingston at Rochester Sunday evening, Aug. 13, for the trip to Montreal. All day Monday as the steamer passed through the Thousand Islands and the famous rapids of the St. Lawrence, old friendships were renewed and new ones formed. It made an ideal start for a week of companionship.

Montreal

Tuesday morning an inspection trip of the magnificent harbor facilities was arranged. Some members also visited the plants of the National Brick Co., Ltd., across the river from Montreal in Laprairie. Excellent common brick, face brick and hollow tile are made at the four plants operated by this company. The common brick plant shown in Fig. 1 has a capacity of about 65,000,000 brick a year. A battery of thirteen dry pans feeds a pug mill and an auger with a wire cutter which turns out brick at the rate of 220,000 to 240,000 per day. Clay is brought from the clay bank, Fig. 2, on dump cars shown in the foreground, Fig. 1. Only half of the building is in use at present, so that the capacity can be doubled when conditions are favorable.

After a delightful lunch in a quaint old French tavern in Laprairie, the main group was rejoined at the Consumers Glass Co., where O'Neill semi-automatic machines equipped with Federal Glass Co. feeders were seen in operation, producing bottles of various shapes and sizes. Certain shapes were also being blown by hand, so that it was possible to compare the two methods. The practice of shipping bottles in bulk by simply stacking them in the cars with a layer of heavy paper between stacks attracted a great deal of attention. Breakage has been found to be extremely low.

Wednesday's activities began with breakfast at sunrise, for the two special parlor cars were attached to the 6:15 train for Ottawa.

Derry Feldspar Quarry

Upon arrival at Buckingham, about 30 miles from Ottawa on the Quebec side of the Ottawa River, automobiles conveyed the party over 10 miles of picturesque roads winding through the east side of the Lièvre River Valley to the Derry feldspar quarry.

This deposit, opened by O'Brien & Fowler in the fall of 1920, contains feldspar which is cream to white in color, analyzing 12.5 to 13.5 per cent potash and 1.75 to 2.15 per cent soda. The deposit has a maximum width of 150 ft., about 50 ft. being practically pure feldspar, while the remainder consists of mixed feldspar and quartz. The richer portion, which is about 300 ft. long, is being worked as an open cut. The method of working is shown in Figs. 3 and 4.

The material blasted from the face of the quarry is inspected as it is placed on 1-ton flat dump cars, small pieces being eliminated through the use of stone-forks in loading. The cars dump into a 100-ton bin on the hillside. Transportation to the railroad varies with the season of the year. In summer, the feldspar is handled 2 miles by wagon to the river and placed in scows, which are towed to the railway siding at Buckingham. In winter, the entire trip is made by sleighs, the frozen river forming the highway for the greater part of the distance.

After a thorough inspection of the quarry under the guidance of the superintendent, N. B. Davis, full justice was done to an excellent dinner served camp-style in the mess hall at the quarry. Many will agree that this was one of the most delightful experiences of the whole trip.

Ottawa

Arriving at Ottawa late Wednesday afternoon, the party registered at the Chateau Laurier and then took dinner at Ye Olde Homestead Inn just across from Ottawa on the Quebec side of the river. Later in the evening several members were conducted through the well-equipped ceramic laboratories of the Department of Mines by Mr. McLeish, director, Mines Branch, and Howells Frechette, in charge of ceramic work.

Thursday morning one of the mills of the E. B. Eddy Co. at Hull, Que., was visited. Products of this mill

include ground-wood pulp and a wide variety of paper and paper products, such as paper bags, tissue paper and crepe paper.

The sulphite mill of this company is shown in the center of Fig. 6.

Richardson Feldspar Quarry

Near Verona, in Frontenac County, Ontario, is located the famous Richardson quarry, which from 1901 to 1918 furnished most of the feldspar shipped to the United States. The quarry is so situated that a series of handlings was required to place the feldspar at the nearest railway spur. Prior to 1918 labor was cheap enough so that a small margin of profit remained after transportation charges. Since then the cost has become prohibitive and the mine has not been operated. The present owner, R. F. Segsworth, of Toronto, who was active in the development of the Seneca-Superior mine at Cobalt, has interested the Canadian Pacific Railway officials so that the spur is being extended to within 2 miles of the quarry. The connecting wagon road is being finished by the Ontario Department of Highways, so that transportation difficulties will soon be a thing of the past.

About 3 o'clock Thursday afternoon the special cars were carefully pushed to the end of the spur extension. The remainder of the journey—a matter of 3 or 4 miles over the crushed rock sub-base of the new road in lumber wagons provided with rough pine boards for seats—was enjoyed most by those who walked up and back. Those who had the courage and endurance to stick to the wagons insist that the distance was at least 10 miles each way. All were amply repaid, however, by the opportunity to inspect one of the largest deposits of high-grade feldspar on this continent.

The extent of the deposit is apparent from Fig. 7. The pit is about 400 ft. long by 150 ft. wide and 100 ft. deep. All told, about 500,000 tons of material has been removed. About half of this has been high-grade feldspar, while the remainder, which requires sorting, has been left in the form of stock piles, one of which is visible at the upper right, Fig. 7. Pending completion of the new transportation facilities, operations at the quarry are confined to working over and sorting these dumps.

In anticipation of a strenuous return trip, several of the party refreshed themselves by a plunge in the clear waters of Thirteen Island Lake.

Kingston

Although an elaborate program of entertainment had been arranged by the Kingston Council, there was only time for dinner at the Frontenac Club and a hurried inspection of the new Memorial Hall before boarding the special sleepers for Toronto.

Toronto

Friday morning the wonderful harbor developments at Toronto were studied at close range from motor launches.

In the afternoon the party divided for plant visits, some going to the Standard Sanitary Works, others to the Jefferson Glass Co. At the latter plant a pot furnace was in operation and large arc light and street light globes were being blown by hand. After passing through continuous leers the surplus glass is neatly cracked off and the edges ground smooth.

Electric lamp shades of almost every conceivable shape and design are made and the decoration of these forms a most interesting part of the operations at this plant. Some designs are brushed on by hand, plain colors are applied by air brush either with or without the use of a stencil, while many designs are obtained by the method used for decorating china. The design is first etched on a steel plate and the lines filled with wax containing the desired pigments. The wax design is then transferred to a sheet of paper, which is applied to the glass to be decorated. The wax adheres strongly to the glass and the paper may be removed, leaving the design ready for burning. All designs are fixed by heating to a temperature approaching the softening point of the glass used.

Before returning to the King Edward Hotel, the parties reunited for a motor bus trip through the beautiful residential sections of the city.

Hamilton

Arriving at Hamilton by boat Saturday morning, the party at once proceeded to the plant of the General Porcelain Co., where the operations in the manufacture of high-tension insulators were explained briefly. An interesting feature was a test of a large insulator at 300,000 volts.

Next the most modern process for making window glass was seen at the Canadian Libbey-Owens Sheet Glass Co. The mixture of raw materials is fed from overhead bins into a regular producer-gas-fired tank furnace having a capacity of about 600 tons. The feed end of the furnace is shown in Fig. 8. At the back end of the tank is the drawing mechanism shown in Fig. 9. Here a continuous sheet of glass is drawn from the pool of molten glass, the thickness of the sheet being controlled by the speed of drawing. The sheet rises vertically for about 3 ft., makes a right-angle turn while still soft over a roller and then passes horizontally through the long annealing leer, emerging at the far end as a continuous sheet of glass about 6 ft. wide. Two men with cutters trim off the edges and cut the sheet into pieces, which are later cut to size and packed in boxes. Fig. 10 shows the leer on the upper level, the boxes of glass below and the loading platform in the center of the building. There are two complete machines at this plant, each having a capacity of from 3,000 to 3,500 100-ft. boxes per week. When drawing ordinary window glass, the sheet is delivered at the rate of about 6 ft. per minute.

After lunch a small group also visited the plant of the Dominion Glass Co., where Owens automatic bottle machines were seen in operation.

This concluded a week which will long be a pleasant memory in the minds of all who participated and one which did much to knit more firmly the bonds of friendship and kindred interest which have long existed between ceramists on opposite sides of the invisible boundary.

What Goes Into Paper

One hundred pounds of paper, according to a compilation appearing in the house organ of a large paper manufacturer, represents the following commodities in approximately the quantities indicated: Wood, 13.4 cu.ft.; sulphur, 12.7 lb.; limestone, 17.5 lb.; kerosene, 5.7 oz.; bleaching powder, 14.3 lb.; rosin, 3 lb.; soda, 0.515 lb.; alum, 4.2 lb.; color, 1.8 oz.; coal, 320 lb.; iron sulphate, 0.79 oz.; copper sulphate, 0.19 oz.; lime, 3.17 oz.; and 7,500 gal. of chemically treated and filtered water.

The Circulation of Molten Metal by Means of Electrodynamic Forces

By Oscar Brophy

IN CERTAIN types of electric furnaces in which the heat is generated by passing the current through the molten metal, it is absolutely necessary that sufficient circulation be maintained in order that the heat will not accumulate in any one part of the furnace. If the heat does accumulate, the furnace will fail to operate successfully, due either to the volatilization of the metal or to the failure of the refractories.

This statement applies to that type of furnace which is composed of a molten metal bath and a molten metal resistor. The metal is heated in the resistor and at the same time circulated into the bath.

Pinch and Corner Effects

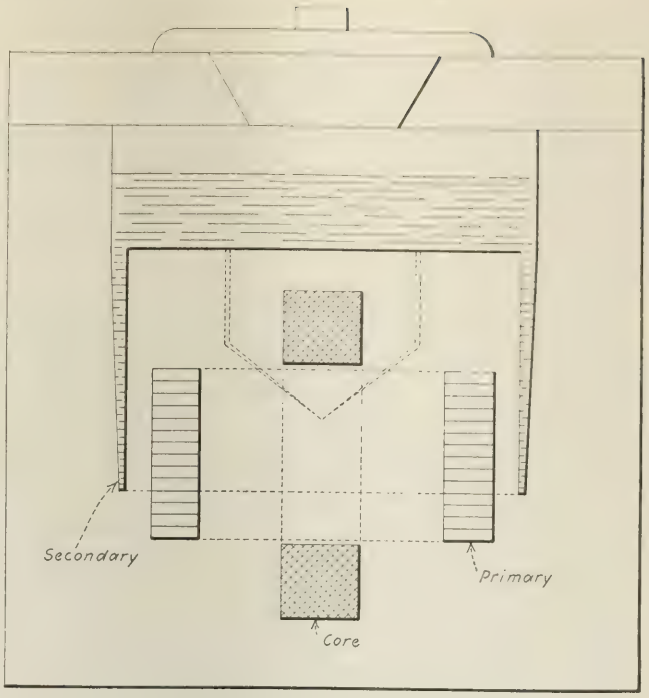
The first furnace of the above type to attain prominence and which depended on an electrodynamic force to attain this circulation was that described by Hering (U. S. Pat. 988,936). This furnace was operated by what is known as the "pinch effect." The explanation of this force which is most easily understood depends upon the fact that conductors carrying currents in the same direction attract one another. Assume that the molten conductor is composed of innumerable strands of molten metal each carrying its current. Then all of these strands will be attracted to one another and will set up a pressure at the center of the molten conductor and cause the liquid metal to flow lengthwise through the conductor.

This "pinch effect" is not dependent on any other external force such as would occur if another part of its own circuit or another circuit entirely were brought near it. We may then say that "pinch effect is the action of a current upon its conductor."

A second electrodynamic force that is used to circulate molten metal is known as the "corner effect" and was also first described by Hering (U. S. Pat. 1,105,656). This force has also been named "motor effect," but this is misleading, because in most types of motors the effect is obtained by the reaction of two separate and distinct circuits, whereas the "corner effect" mainfests itself in a single circuit. Whenever a liquid conductor carrying a current is made to take the form of an angle there is a force set up in the liquid. This force is strongest at the apex of the angle and decreases as one recedes from the apex. This force depends upon the fact that conductors carrying currents in opposite directions repel each other. Here the turn of the conductor gives the condition of two conductors of the same circuit carrying the current in opposite directions. We may then say that "corner effect is the action of a current upon a conductor in another part of the same circuit."

Motor Effect

A third electrodynamic force that can be used to circulate molten metal is that set up between the current carrying conductors of two separate circuits. The method of using this force in an electric furnace of the resistor and bath type was first described by the writer (U. S. Pat. 1,296,752) (see figure). This force is made use of in the constant current transformer in which the primary coil of a transformer is made stationary and the secondary coil is permitted to move in a vertical direction and is balanced by weights. The current flowing in the secondary coil is in the opposite direction to that of the primary coil and therefore there is a repulsive force between them. By adjustment of the balancing weight a certain current only is permitted to flow in the secondary coil. If the current should tend to increase, the repulsive force between the two coils will move the secondary coil away from the primary coil and cut down the secondary voltage.



This force was a detriment in the old open channel induction furnace. It tended to repel the molten metal from the primary coil toward the outside when the primary was placed inside the molten secondary. This force was so great as to cause the inclination of the bath of an 8-ton Kjellin furnace to be about 24 deg. (*Stahl und Eisen*, 1910, p. 1071). The uneven level of the metal caused the slag to run always to the inner side of the channel, where the refractory was quickly destroyed.

The action that takes place in most types of electric motors may properly be said to be due to the two separate circuits therein. Therefore this electrodynamic force may be properly termed "motor effect."

We may then say that "motor effect is the action of a current in one circuit upon the current carrying conductor of another circuit."

There is one characteristic of these three forces that it may be well to state. In what parts of the circuit can each force manifest itself? The "pinch effect" will show itself in the resistor or restricted part of the circuit. The "corner effect" will show itself only at corners in the circuit, but the third effect may show itself in every part of the circuit, if properly designed. This is desirable, as the more circulation the more efficient will the furnace operate.

Conclusions

In conclusion, there are three important electrodynamic forces that may be used to circulate molten metal: 1 Pinch effect. 2. Corner effect. 3. Motor effect.

Pinch effect is the action of a current upon its conductor. Corner effect is the action of a current upon a conductor in another part of the same circuit. Motor effect is the action of a current in one circuit upon the current carrying conductor of another circuit.

Notes on Iron Ore Smelting in California

Pig Iron Was Made in a Small Blast Furnace Operating at Clipper Gap in the Early '80s, and More Recently in an Electric Furnace at Heroult

By R. C. Gosrow
Consulting Metallurgist

SHORTLY after the gold rush in 1849, the necessity of developing an iron industry was foreseen by many of the early pioneers. California was the center of mining activity, and the transportation of iron from England and Scotland and the Eastern United States was slow.

In 1867 the "cost of importing pig iron from Europe to San Francisco was $40 per long ton;" the freight rate varied from $12.50 to $15 per ton. The word "cost" is taken from the old record, and it is assumed to mean the price of the iron laid down in San Francisco. The freight on iron from the Atlantic Coast was $12 to $16 (U. S. currency) per long ton. In 1867 Australian iron cost $40 (gold) per long ton at the wharf in San Francisco. Iron imports in 1866 were 9,388 tons; and for the first half of 1867 they were 2,063 tons.

California naturally had a limited demand for iron products. In 1850 the population of California was only 92,597; in 1860, 379,994; and in 1870, 560,247. In 1880, when the first real smelter was built, the population of the state was 864,694. So from the time the first interest was taken in iron ores and iron production in 1869 up to the actual building of a smelter in 1880 the population of the state had increased 54.5 per cent.

First Location of Iron Ore

In 1854 a deposit of iron ore was known, and had been given some attention on account of its surface croppings, near Clipper Gap, in Placer County. This deposit first had the attention of S. W. Lovell, at that time president of the Bear River Water & Mining Co., and was described by J. Ross Brown, Washington, 1868, in a report on "Mineral Resources of the States and Territories West of the Rocky Mountains," p. 223:

"Robinson, Brown & Co.'s iron mines are located here, about 3 miles from the railroad and 3 miles from the Bear River. These mines were located and patents for the land from the federal government applied for in May, 1866. The company purchased the title of the railroad to the even sections of the land, to the extent of 1,500 acres . . . The ore crops out from the mountain in many places. There are two qualities in the deposit; on the east side it is highly magnetic, while on the west it is very much like the Oregon limonite. Assays made by Kellog & Hueston of San Francisco in March, 1866, gave the following results: the magnetic ore, 64.37 per cent metal; the hematite, 44.67 per cent metal. Professor Jackson of Boston, Mass., states that it contains no phosphorus, sulphur, titanium or other substances injurious to the manufacture of iron . . ."

Early Developments

In order to determine just what might be expected in the smelting of this ore, it was arranged with Coffee, Risdon & Co. to erect a furnace on the property to test out the ore on a practical scale. After many urgent efforts the scheme was abandoned. In June, 1857, a sample of the iron ore from the Lovell property was sent to San Francisco for testing. In tests run on this sample it was found that the ore "yielded 83 per cent iron." Nothing more was done with this property for many years, and although the property was inactive, its early publicity seemed to promise more for the state.

From 1858 to 1862 very little is reported on the development of iron ore mining. In 1862 and 1863 several deposits of iron ore were reported in Sierra County and elsewhere.

In 1867 magnetic iron ore was found on Grouse Ridge, 14 miles from Washington, Nevada County. Magnetic ore was also discovered near Chapparal Hill, Butte County, near Grizzly Creek; it was reported that this ore contained 65 per cent iron. In Sierra County the ore deposits were considered of great value. A deposit was discovered by its surface croppings 12 miles from Downieville at an elevation of 6,200 ft. Baron von Richtoven said of this ore in a report to the owners: "Your mines consist altogether of magnetic iron ores, and the same as from which the celebrated Swedish and Russian iron is manufactured. A total amount of ore which may be extracted from different deposits by quarrying I estimate to be 1,400,000 tons—average yield 45 to 50 per cent iron. Even the removal of the ore next to the surface will be the work of a generation."

In 1869 the firm of Robinson, Brown & Co. shipped ore from the Clipper Gap mine to the Pacific Rolling Mills in San Francisco. It was reported 20 tons was shipped in July of that year. No analysis of the ore is given in the records.

First Incorporation

In December, 1869, a company was incorporated in San Francisco, under the name of the Iron Mountain Iron Co., with a stated capitalization of $500,000, and was composed of the following men: J. R. Brown G. W. Applegate and A. G. Neal. They are described as "men of limited means." The purpose of the company was "the mining of iron ore and the smelting of pig iron." This was over 15 years after the deposit was first discovered, and the year following Mr. Brown's examination.

As pig-iron manufacture was a new industry in California, it was expected it would need all the support it might be possible to acquire to encourage its establishment and growth. State legislation was one of the means considered suitable, and in February, 1870 Assemblyman Waldron of Placer County presented a bill known as "An act to encourage iron mining." The provisions were: that when the company had reduced 2,500 tons of merchantable pig iron the state should

pay the company a bonus of $12 per ton; also, the state should pay to the company annually for 10 years an amount of money equal to the taxes that would be due on iron and products of the mine, if they were assessed at the market value in San Francosco; and refund to the company money paid as taxes on its other property. The bill also gave the company 5 years in which to produce the 2,500 tons of merchantable pig iron, and in default of such production the state did not pay the company anything. Gov. Haight vetoed the bill.

Like many new enterprises, the company was short of the necessary capital to carry out its program. It was forced to discontinue, and the ore was left to remain in the hills. But in 1874 a Mr. P. Fitzhue came to examine the property at Clipper Gap. His interest was derived from reading the report of Professor Whitney, in his volume on the "General Geology of California." Plans were laid for the formation of a new company to work the property, but nothing of note was accomplished until 5 years later.

Blast Furnace Built at Hotaling

In 1879 the California Iron Co. was incorporated by E. Judson, A. P. Hotaling, Mr. Scott and Mr. Fitzhue. This new company purchased the property at Clipper Gap and at once commenced the construction of a smelting plant, and the establishment of a town site, called Hotaling, 3½ miles from the Central Pacific R.R. In 1880 this company erected a modern blast furnace at the property, with the necessary buildings, to carry on the mining of iron ore and the smelting to pig iron.

The blast furnace was constructed on the same lines as a furnace at one of the South Chicago steel plants, but was smaller in size, having an expected production per 24 hours of 25 tons. The stack was 47 ft. high, 13 ft. in diameter and had five tuyeres. The furnace building was 150x200 ft., and accommodated thirteen pig beds. A 135-hp. horizontal blowing engine supplied 4,000 cu.ft. of free air per minute. The pressure at the tuyere is not given. Blast was heated in a stove, consisting of 56 tons of iron tubes, heated by furnace gases. Marble was available for flux. The reducing fuel was pine charcoal made from local woods. The company operated three charcoal camps, 3, 6 and 8 miles respectively from the works. The kilns were the beehive type, 29 ft. high, 32 ft. in diameter, and held 45 cords of wood, producing 2,250 bu. of charcoal from a charge. Production figures cannot be derived, but as the furnace had a production of a ton of iron per hour at least 30 tons of charcoal was needed per day.

The first iron was tapped on April 24, 1881. A typical charge was: ore 800 lb., marble 30 lb., charcoal 500 lb. From this charge the charcoal to pig iron was 1 to 1, or a ton of charcoal to a ton of pig iron. The pigs cast weighed 90 lb. each. Labor at the plant was distributed as follows:

Furnace hands	50
Mining ore	40
Charcoal burners and teamsters	75
Incidental	12
Total	177

The grades of iron produced were Nos. 1, 2, 3 and 4 foundry; some forge iron was also made. This iron brought $8 to $10 a ton more than Eastern iron in the local markets.

In September, 1881, the foundry and the machine-shop buildings were destroyed by fire and the plant was temporarily closed down. It was the intention to resume operations in the spring of 1882, but the plant was not opened up again, and the California Iron Co. retired from business in the latter part of 1882.

During the operations from April 24 to the closing down of the plant in September, 1881, 4,414 tons of pig iron was produced, an average of 800 tons a month. Records do not say, but in all probability the greater tonnage was shipped to San Francisco and the iron foundries around the Bay.

The operations of this company were attended by many adversities. "Some of the construction work was defective and required being done over." Many blunders were made in the design of the equipment, as well as in operations, all of which absorbed the profits of the venture.

The California Iron & Steel Co. succeeded the California Iron Co. in 1882 with the intention of enlarging the scope of operations by producing steel bars and shapes. There seem to be conflicting records on further operations at Clipper Gap smelter. One record states: "In 1882 production was somewhat larger than the preceding year," but the "History of Placer County" states that the smelter closed in 1881 after the fire and did not resume operations. While 1,002 net tons of iron ore was produced in 1882, it did not necessarily go into pig-iron production, as the lead and copper smelters used considerable tonnages of iron ore. By this time there were also some steel furnaces in San Francisco.

Rolling Mills in San Francisco

An outlet for California-made pig iron was a certainty. In May, 1866, the Pacific Rolling Mills was organized and in July, 1868, the first bars were rolled. In 1881 this works employed, together with other iron-working establishments in San Francisco, 1,200 people. Eventually the company consumed 18,506 tons of pig iron annually, and produced 16,500 tons of bars. The Benicia Agricultural Works made plows and agricultural machinery; it melted the Clipper Gap pig "with a little Scotch mixed in to get the best combination of toughness and hardness." A plant in Oakland was also run in connection with the Clipper Gap mine, converting its product into iron and steel.

In 1880 there was imported into the state 13,200 tons of pig iron. Pig-iron consumption in California is given at 12,250 tons in 1881, of which 4,500 tons was produced locally, and the remainder imported. The value is given at $337,000, or $27.50 a ton. From 1875 to 1880 the average price of pig iron in San Francisco was $29.75 a ton. With locally produced pig iron, furnace owners promised to lay iron down in San Francisco for $24 a ton. With the Clipper Gap iron selling at $8 to $10 a ton over Eastern iron, a good profit must have been made on this iron at $33 a ton for No. 3 or 4 grade.

Noble Steel Co.'s Operations on Pitt River

In the following years some new deposits of high-grade iron ore were discovered. Notable among these was the Pitt River iron mine in Shasta County, near the Pitt River, a rich magnetic iron ore, averaging 65 per cent iron with under 0.02 sulphur and 0.02 phos-

phorus. The Herz Mountain deposit contributed iron ore to the Bully Hill copper smelter, as did the Pitt River iron mine also.

No developments on a commercial scale took place until 1907, when H. H. Noble of San Francisco formed the Noble Electric Steel Co. to smelt the Pitt River ore by the electrothermic process. Dr. Paul T. Heroult was engaged to come from France and design and build the first furnace. The townsite, named Heroult, was located 8 miles from the junction with the Sacramento River.

Initial operations at Heroult were coincident with the development of large waterpowers on the west slope of the Sierra Nevada Mountains, and within a short transmission distance from the proposed smelter. It was hoped to convert electrical energy into heat in a proper furnace and smelt the local iron ore to pig iron. Adjacent to the iron ore there was a deposit of pure limestone for flux, and the wooded hills presented a supply of wood for charcoal. In 1908 the first furnace was completed and put in operation. A plant was built later to make charcoal from pine wood, and to recover the byproduct.

Experiments With Electric Furnace

The first electric furnace was a rectangular type of furnace with three electrodes—large blocks of carbon, built up from smaller pieces. No one in this country was making carbons of the size required for this furnace, and as a consequence they had to be imported from Europe. Many interferences developed, and this furnace was operated intermittently for only about 3 months.

From 1909 to 1911 a new furnace was developed of the circular type, using a superimposed shaft down which the ore and charge descended to a larger crucible below. The electrodes entered the crucible at an inclined angle, through a dome-shaped roof. This furnace had an electrical capacity of connected transformers of 1,500 kva.; it produced about 10 tons of foundry iron daily, consuming on an average 0.34 hp.-yr. per ton of iron.

In 1911 the furnace was changed back to the rectangular type, but instead of the straight delta connection with the three electrodes in a line as in the first furnace of Dr. Heroult, the furnace had four vertical graphite electrodes in a straight line, and the delta connection was open, with the first and fourth electrode at the ends.

This furnace presented many features which required perfecting before it could be pronounced a success. The transformers connected had a capacity of 2,250 kva., but certain power conditions required the installation of a fourth 750-kva. transformer on one phase, to carry a circulating current due to low power factor. It was difficult to feed the furnace properly and keep the stacks open for the charge to come down into the furnace. Hang-ups in the stacks caused the refractory arches through which the electrodes entered the furnace to burn out. No end of delay was caused by such improper feeding. Often, after a hang-up the charge would drop and break an electrode.

Throughout 1911 and 1912 the features which caused trouble were gradually eliminated, and the furnace steadily produced 20 tons of foundry iron a day. Power consumption was about 2,700 kw.-hr. per ton of pig, and the furnace averaged 20 hours a day on load. In 1913 a second furnace of the same general design as the one just described was built, with six 750-kva. single-phase transformers (two transformers on each phase connected in multiple). The furnace was 27 ft. long, 10 ft. wide and 10 ft. deep from the bottom to the electrode holder. It was operated through the winter of 1913, but closed down in the spring of 1914. Severe power troubles in the mountains caused many delays in the winter of 1913.

In 1913 the company built a modern twenty-retort byproduct charcoal plant; to supplement this production some charcoal was purchased from Mendocino County.

All through these operations on pig iron the fact was demonstrated that for an electric furnace to produce a concentration of heat, a steady, even feed of the charge must be provided; electrically a constant load must operate over a constant period of time. The best operations showed 5 per cent of delays; "power-off" was the worst interference—it always took at least twice as much time to come back to normal working. In 1914 the company ceased making pig iron and turned its plant over to ferromanganese.

This plant at Heroult presented many advantages as well as disadvantages for the production of pig iron. It was considered that the proximity of power, ore, limestone, wood and transportation would assure the commercial success of the enterprise. Situated only 280 miles from San Francisco and the Bay cities, a market awaited the product. Being in a region where other smelters were operating on copper ores, skilled labor was available. But many things acted with equal force in the opposite direction.

Possibilities of Electric Smelting

Electric smelting of any ore was a new branch of metallurgy. There existed no precedents derived from the experience of others in this particular art. No one knew of the fitness and adaptability of the proposed equipment; if unsuitable, it was discarded before its use had even paid for itself. Another serious handicap was the difficulty of obtaining men to design and build the equipment. The decision to smelt iron ore in an electric furnace patterned after the shape of an iron blast furnace did much to delay the development of the right type of furnace. Reactions in the electric furnace take place in an entirely different way than those in the blast furnace, and this caused many mistakes in the grade of pig produced. Often when foundry iron was wanted, white iron resulted. Shortcomings in the electrical equipment often caused much trouble, so that the required load to generate the necessary smelting heat could not be carried. Charcoal was considered to be the ideal fuel on account of its bulk, its electrical resistance, its freedom from sulphur and phosphorus and its availability. But the cost of even byproduct charcoal was so high that when 800 lb. of charcoal was required per ton of pig iron, it made the price of pig too high for local purchasers.

When electric pig iron was first sold to foundrymen, they objected on account of the close grain as compared to blast-furnace iron. They graded the iron on fracture, and the electric iron was sold on analysis. As the fractures did not compare for the same silicon and sulphur contents, the foundrymen were skeptical. This prejudice had to be overcome, and it eventually was.

As byproducts from oak wood are more valuable than the byproducts from conifers, it was not possible or feasible to get sufficient oak, so the cost of the charcoal was higher than it should have been.

However, electric pig iron, wherever it was used, produced castings of extreme fineness and softness. Foundrymen liked the iron, but unless they could get a higher price for their castings made from electric iron, they would not buy it. As a consequence electric iron had to be sold in competition with Southern and Midwest blast-furnace irons. Often foundrymen used electric pig to mix with other irons when they had particular castings to produce.

These and many other causes contributed to the circumstances which made the establishment of the electric smelting process so difficult and so slow.

It must be considered, however, that in the early years at Heroult the process was by no means a commercial one. Production of pig iron was carried on under restricted schedules, during which time the correct furnace was evolving. Simultaneously the development of the company's iron ore property was going on, and in 1914 there was enough ore blocked out with an average iron content of 65 per cent to run the smelter 50 years on a 50-ton-a-day basis. With the development of the Pitt mine, the mills in and around San Francisco purchased this ore for their open-hearth and other furnaces. It was mined in an open pit, and delivered to standard railroad gondolas a mile distant.

With the World War instigating every metal producer to do his utmost, the company went into the manufacture of ferro-alloys in 1915, and did not again produce pig iron, with the exception of a small amount made in some experimental work. During the Noble Electric Steel Co.'s operations on pig iron during 1911 to 1914, it produced approximately 3,500 tons of salable pig iron. The charcoal ratio to pig iron was about 1 to 2.5.

Reduction of Iron Ore With Fuel Oil

Just prior to the electric smelting operations at Heroult in 1907 and 1908 there were many attempts made to reduce iron ore by the use of California fuel oil. While these efforts never developed beyond the experimental stages, historical mention should be made of them. Generally the idea was to utilize the fuel oil as the prime heating agent, and by the use of pressure or suction force the mixed oil and air into the furnace through a tuyere. Experimental furnaces were often built along the general lines of a vertical blast furnace, and fed through an air-tight bell at the top. Many types of burners were used, so that the correct mixture of air and oil might be taken into the furnace. Reducing material was charged separately with the ore. These processes were never a metallurgical success, because the reduction of the iron ore in such a manner could not be controlled. Instead of reduced iron being tapped, the furnace more often discharged ferrous oxide and an iron silicate slag.

Contemporaneous with these attempts experiments were carried on to reduce iron ore to sponge iron, and then melt the sponge iron to steel in an electric or other furnace. One such installation comprised a 15-ton, double three-phase electric hearth furnace, with a gas outlet in the side above the metal bath. This gas outlet was connected to a hopper-bottom concrete tower, about 20 ft. high and 42 in. in diameter lined with refractory brick. It was attempted to reduce a charge of iron ore in the reducing tower to an iron sponge, draw off the iron sponge, charge it in the electric hearth furnace and melt it, and build it up to the desired steel analysis required. Gases from the reactions in the steel furnace were to furnish the heat required to reduce the ore in the stack. After the first charge was made in the reducing stack, the process was started and the cycle was supposed to repeat itself. This process was in actual operation, and while the metallurgy of the process was simple, yet the mechanical features were far from a success. The charge in the reducing tower partly fused and the whole mass would hang in the tower and prevent further gas circulation. Due to the heavy expense of conducting experiments on such a scale as this, and with the small measure of reward, this process was discontinued.

Dreamers, and even metallurgists, had hoped that in some way a process might be revealed to them that would bring together iron ore and California fuel oil in such a manner that pig iron would result. Types of equipment of every conceivable design were proposed in patents and plans by those interested. No attempt is made to list these; only those that have actually been tried on a considerable scale have been referred to. None of these schemes has consumed enough iron ore to classify it as a commercial process.

Present Situation

Thus, in California there have been only two plants which have really entered the market as commercial enterprises. These two have been described in some detail, even though neither is now operating. Other plants, including the steel plants in the Bay region and in southern California, have tried direct reduction of iron ore, but nothing has yet resulted from these experiments. As consumers of iron ore, and one might say in the broad sense "smelters" of iron ore, the steel mills are the largest, so that outside of some chemical industries the steel furnaces now consume practically all the iron ore mined in California.

The iron ore resources of the state are quite well outlined in several bulletins issued by the State Mining Bureau. Principal among the potential iron ore properties are deposits in San Bernardino County, in the Eagle Mountains, the Minaretts of Madera County and the Placer County and the Shasta County deposits. Given shipping facilities from any one of these to tidewater, a reduction plant could operate on a scale large enough to furnish the Pacific Coast with its pig iron.

Catching Zinc Fume

At the recent Vancouver convention of the American Institute of Electrical Engineers, it was stated by E. P. Dillon, general manager of the Research Corporation, that it has now become possible to catch zinc oxide from furnace gases. An application of recently discovered principles (described by Evald Anderson in this journal, Jan. 25, 1922) has made successful several commercial installations handling up to 20,000 cu.ft. of gas per minute, at temperatures as high as 700 deg. F. The fume content of these gases has been as high as 5 grains per cu.ft. (standard conditions).

It is necessary to "condition" these gases by adding steam or water. Even from these humid gases the deposit comes down dry.

The Dye Situation in Great Britain and Elsewhere

A Survey Based on Authoritative Information Gathered by the Author at First Hand in England — Outline of German Proposals to Participate in Dye Industries of Other Nations

By Ellwood Hendrick

IN GREAT BRITAIN they have the British Dyestuffs Corporation Ltd. besides Scottish Dyes, the British Alizarine Co. and one or two others making specialties. British Dyestuffs is the leading company. In France there is the Compagnie Nationale des Matières Colourantes; in Italy there is a somewhat similar establishment, and what we in America have the Lord knows. In Germany there is the Interessengemeinschaft der Deutschen Farbstoffwerke, or the I.G. as it is called.

British Dyes started during the war with a great blow of trumpets and a large expenditure of money, taking in the works of Read Holliday's Sons at Huddersfield, and building elaborately, expensively and in haste. At the same time Levenstein's Ltd. of Manchester waxed great, the works extending over a mile in length, with about 3,700 men employed. In the course of time Levenstein's Ltd. was taken in. British Dyes became British Dyestuffs Ltd. and a dual management was established, with Sir Joseph Turner of the former Holliday concern to look after business matters, including purchases and sales, and Dr. Herbert Levenstein, an acknowledged authority in the subject of dyes, as technical head. The British Government had a large investment in the works and has had considerable to say in recommending appointments.

Changes in Management

Levenstein's Ltd. and Read Holliday's Sons had always been rivals and Dr. Levenstein and Sir Joseph Turner were not meant to work as a team in double harness. But development proceeded. Professor Green, discoverer of the primaline dyes, was retained for research, and Professor Robinson, who is said to be a second Emil Fischer in organic chemistry, was also brought in for the same purpose. There was lacking, however, any co-operation between research and manufacture with the department of sales, purchases and business. So Dr. Levenstein tendered his resignation unless Sir Joseph Turner were replaced by somebody he could get along with. Here the guiding voice of the government urged harmony and waiting, until an impasse was reached and then both Dr. Levenstein and Sir Joseph Turner were replaced by Sir William Alexander, the present head.

Sir William is a man of signal ability in business affairs. He has been largely interested in the making of heavy chemicals, was closely assosiated with K. B. Quinan in the manufacture of munitions during the war, and has been heretofore signally successful in all his undertakings. He is a man of high character and reputation. He found that research had so far outstepped production that about 20 per cent of the research chemists were dismissed. Manufacture was reduced so as to be made co-ordinate with sales, and for the general works manager, C. J. Burnham was selected, a gentleman who had been successful in the production of munitions in England during the war and associated with Quinan in making explosives in South Africa and India. The sales force was generall reorganized and co-ordination of research, manufactur and sales departments was established. The variou men in authority in the three departments of researc manufacture and sale now meet with the managin director every Wednesday and work is planned ahea with a view to meeting every need as it arises. Ne dyes are introduced as soon as factory practices, even ness of quality and the satisfaction of all three depart ments are attained—and not before.

British Public Supports Industry

Now it is a long, long road to Tipperary and t several other places, among which is the goal of makin dyes for the British or any other market in the fac of German competition. Even with the 10 years' em bargo, when Germans offer goods at an amazingly lo price—at a dumping price—the temper of manufactur ers and of the dye commission is strained. But th British public is alive to the fact that, given complet failure of the industry in England and America an elsewhere outside of Germany, and given also the suc cess of the Junker Partei in Germany (under whateve name it functions), then the next generation is likel to know what gas attacks mean as never was know before.

The position which Sir William Alexander is strain ing every effort to attain, and it goes without sayin that he is bringing all his great abilities to this end is to keep the good will of British dye users so that the will take native dyes in preference to those of Germa make, provided always that they are as good and a regular as German goods, *but not otherwise*. In regar to prices he holds it to be his obligation to meet th needs of British dye users before the interests of stock holders are considered. Further in regard to prices he holds that these should be standard for the sam dyes over the whole world. He is willing to make inter national trust agreements as to quotas of sales an markets, but provided only that the British corporatio remains inviolate as it was founded: a dye-making con cern. If such agreements cannot be made adequate t British needs, both in peace and in war, then the profit of the business are bound to be small all around, bu he has faith that the industry will still endure in Grea Britain.

At the annual meeting held on June 23 there wa shown profits on operations for the year of £437,683 but owing to reductions in stock values the management wrote off £1,444,343, indicating a loss of £1,006,660, bu leaving cash assets in excess of £1,000,000. The meet ing was not harmonious, although the regular ticket wa elected by about two-thirds of the shares represented Dr. Levenstein, who is the largest shareholder, refuse to make any comment on the chairman's report on th ground that the corporation's best interests would b served by such a course.

The opposition held that the corporation now lack

proper scientific and technical control. The dye industry, according to the opposition, differs from others in that it is an establishment of standardized processes rather than products, which must frequently be supplanted by new dyes, and that it is, therefore, always in a state of flux. Novelties must be brought out, not only for profit but for the welfare of users of dyes. Again, far greater patience and faith are required than in making other products; and any attempt to organize this industry along lines familiar to other branches of manufacture except, perhaps, fine chemicals, cannot succeed. The management holds that provision has been made in these respects.

Sir William Alexander declares that government participation in the corporation is in no sense a burden and that indeed from the government he gets the very strongest support. This is fortunate, because in the formative period, according to current expression, the hand of the government was heavy, appointing men to represent it and in authority who were wholly uninformed as to the needs of the business. In other words, it made political appointments. Of course, the only way to make progress in this very complex industry is to let the real leaders develop themselves and then to recognize them as such.

Conflicting Views on British Dyes Ltd.

Now, in England, one hears conflicting stories about British Dyes. One is that they are working along against serious odds, but that they have the backing of the color users, that they are proceeding under sound business administration, with good *esprit de corps* and general good will and the advantage of a license system with 7 years to run. They are overcapitalized as a result of war conditions and mistakes, rather than of high finance. They are proceeding on good principles of business, but from many sides one hears the criticism that the weak point is in technological experience. They lack any outstanding dye technologist such as one may find in every works that has achieved success. They are starting largely without experience; with no one like J. F. Schoellkopff 3rd or Dr. Herbert Levenstein to look ahead for them.

Now let us take an entirely new view of the problem. On July 20 the *Chemiker Zeitung* (No. 86, p. 656) contained the following note: "Farbstoffe: The efforts of the I.G. to close a contract with the English works similar to that closed with the French and Italian works (cited from *Chem. Zeit.*, 1922, pp. 404 and 448) has thus far not resulted in any definite conclusion. The first meeting took place, according to the *Yorkshire Evening News*, shortly before Christmas in 1921, in Paris, at which Carl Weinberg of the I.G. and W. Alexander of the British Dyestuffs participated. In May of this year they met again in Berlin, at which Lord Ashfield, the government representative of British Dyestuffs, was also present. Now the Englishmen await new proposals from the German representatives, inasmuch as they are not disposed to conclude any arrangement which will place the English industry where it stood before the war. And the conclusions of the British representatives will require also the approval of their own government."

Franco-German Working Agreement

Of course that does not tell everything. In the *Times* of London on Aug. 1 there is an article headed "French Dyestuffs, An Alarming Rumor," and there follows a quotation from the annual report of the Compagnie Nationale des Matières Colourantes as follows:

> The work of even the best technicians must be sterile unless they are in possession of all the knowledge accumulated in the past—knowledge which is essential to success. All who understand the complexity of the manufacture of organic coloring matters will realize why we have been compelled to acquire the patents, the processes, and the technical aid of our principal foreign competitors for exclusive use in France. Thus we have at our disposal the results of 50 years of investigation and processes minutely studied and methodically put into practice, and so we are immediately placed in a position equal to that of the most modern and most specialized firms in our industry.
>
> Certain sections of the French press affect to perceive in this statement confirmation of a rumor long in circulation that the Compagnie Nationale has entered into an alliance with its German rivals.
>
> It is recalled that not long ago the *Chemiker Zeitung* announced that an agreement had been entered into between the German and French dye industries, in which seven great German firms and the Compagnie Nationale des Matières Colourantes were associated, by which the German firms were to give the French company detailed technical assistance and full information concerning the processes of manufacture and to supply German chemists to supervise the application of the processes in French dye works. In return, it was stated, the Compagnie Nationale undertook to limit supplies of certain synthetic dyestuffs to France and her colonies, and to allow the German firms a share of the profits.
>
> There is therefore a national anxiety to know to what extent the French industry is dependent upon foreign, and particularly German, aid.
>
> It is not merely a question of supplying French industries with French dyes. It is remembered that before the war the dyestuffs factories in France were in the hands of Germans. When war broke out there were neither materials nor workmen to produce dyestuffs, and in consequence no adequate provision for the manufacture of asphyxiating gas and explosives. If the Compagnie Nationale ceased to manufacture dyestuffs, it is argued, and if the day should again come when the rapid manufacture of explosives is necessary, France would find herself unprepared as she was in 1914.

This confirms the statement of the *Chemiker Zeitung* as to the agreement between the I.G. and the French company, and we learn from competent authority that the working agreement is already closed.

Will Government Approve an Agreement?

A subject that one hears occasionally discussed is whether the I.G. and British Dyestuffs will come to some similar agreement and whether, then, the government will approve. In Sir William Alexander's address to the stockholders he said in regard to this: "While we would welcome an arrangement with the German undertakings, it must be on such terms as will leave inviolate the principles on which your undertaking was founded—namely, the establishment of a dye industry adequate to our needs both in peace and in war. So far, however, the German interests are not of the opinion that circumstances are such that they are prepared to accept the fundamental principle which we have laid down as a basis for close negotiation."

An opinion that one hears occasionally expressed at clubs and over lunch tables when the subject is brought up is somewhat to this effect: "The Germans are beaten in war and it is up to them to make good. We don't want their steels or their textiles, because by taking them we cause our own mills to shut down. Real money they haven't got, and yet they owe for damages. Very well, let them pay in giving over their 40 years' advantage in dye-making experience and mark off some of their debt by the operation. Within the past 2 months this

idea seems to have gained some currency, but the writer is unable to record how widespread or how generally it is held or whether such a thought has been touched upon in authoritative conferences.

The German idea seems to be to establish a British working agreement similar to that closed with the French and Italian companies: the I.G. to remain German and the other corporations to remain native with no exchange in ownership of stock. Information to be made common property and chemists and engineers familiar with processes to be transferred back and forth as needs arise. The *quid pro quo* to be a division of the profits before payment of dividends, and allotments of tonnages and territory to be agreed on, all for a long term of years. It makes the I.G. the nucleus of an international industry, participating already in that of France and Italy and prospectively with that of Great Britain. It is evident that on this basis the minds of the British and German negotiators have not met.

We do not know what arrangement has been made between the I.G. and the French company in regard to products or processes that may originate in the French company's laboratories or works.

Now let us do a little guessing. Suppose the minds of the British authorities and those of the I.G. should meet as to terms. The British Government, with its large interest in the enterprise, would have to approve. It dare not proceed too sharply counter to public opinion. And what has public opinion to say?

Are the Germans Sincere?

Here, for instance, is a question that one hears frequently today and that may be asked with persistence when the problem at issue is discussed: Are the Germans to be trusted? In England as in America the impression is widespread that the Germans have done things of which civilized people would be ashamed, and if they do not know it was wrong it is because they do not know what other people do know in the art of living at peace with the world. Time was when Germans were hailed and made welcome almost everywhere; now they are, in a way, *declasée*. Germans do not admit this; against the charge that they should be ashamed they claim that they are an ancient and a proud race, but all the time they know of their inhibition and it hurts.

Today they are a crippled people and they want to get back into the sphere of international comity. Without admitting fault or wrong, they admit this much. International agreements in so overadvertised a domain as dyes would help to bring it about. But is that all? How does the German mind work? Do they propose to fall on the necks of their late enemies and give them of their best, their most cherished possession, to establish an era of good feeling? To make a great gift and then to hope for the best? The German mind is addicted to habits of careful planning and to the study of situations, according to its lights. Therefore, to a proposal so loosely drawn as this appears to be we should expect lively objection from Hugo Stinnes, Professors Duisberg and Nernst, from General Ludendorff, Herr Helferich, "Organization C," the "Selbschutz" and associations of professors and teachers and leaders of German thought who seem unanimous about the "crime of Versailles."

So let's do a little more thinking about the subject. The wealth of a nation is not in its dye business. To forego profits on some goods exported and to get part of them back on goods made and sold abroad is not such a great loss. In view of the present difficulties of export the German proposal might involve no loss at all. And surely international agreements would do more than anything else to bring about international comity.

But future warfare is chemical warfare. Politicians do not know this outside of Germany. Neither do the majority of military men—outside of Germany. The Germans failed to take Calais because even their own military leaders did not know it when they made their first gas attack. And what would ensue from the participation of the German trust in this key industry of other nations? Observe, please, it is not proposed that allied industrial corporations participate in the I.G. The German trust would then be posted as to the situation in, and the facilities of, every other country.

Success in Chemical Warfare

Now the philistines are right when they say that making dyes and intermediates does not alone provide for offense and defense in gas warfare. Offense in gas warfare is provided by the capacity and equipment to produce in great quantity unknown gases of great lethal power for a strategic surprise. Knowing the gases and even how to make them does not meet the conditions. Gas warfare as it is developing is more sudden, more violent and more unexpected than any other method. The only way to succeed in gas warfare is, first, to be willing to launch it and second, to be in complete readiness. Germany is the only nation equipped to fulfil the second requirement of readiness. Her position in regard to chemical warfare is similar to that of Great Britain's sea power for many years, except for the fact that battleships and cruisers are growing obsolete while aircraft and chemical destructives are still undeveloped.

Well, what of it all? Is Germany going to war again? Herr Stinnes, the late Dr. Rathenau and others have tried to avoid clashes with other nations. The old military crowd and the same old government bureaucrats seem impatient to re-establish the empire, to "lead the world" again. But even so, what of it? Suppose such international arrangements are made: it will aid toward comity if Germans with fevered brows can be kept enough in the background. Suppose, on the other hand, they are not made. The leadership in dye technology enjoyed by the I.G. leaves them still at the head. German works will be able to produce gases in quantity for a strategic surprise just as well as but no better than before. British Dyestuffs will have a long, hard pull to go it alone. The good will of other peoples, so frankly desired by Germany, will be much slower in coming to them.

Whether it is wise or not to make such treaties as have been made by the French and Italian corporations the writer of these lines does not profess to say. The question "Are Germans to be trusted?" like the proposed manufacturing agreement, is in the air. It seems better to us to trust them than to mistrust them—provided the trustor can keep awake and has sharp eyes. But far more important than dye agreements for each nation that would be free and always in a position to defend itself is the intensive study and understanding by her sons of the science of chemistry. Without this knowledge, this understanding, this prescience of what chemistry can do, we shall all be at the mercy of any people that prepares itself adequately and secretly to conquer the world.

Rapid Calculation of Theoretical Maximum Temperatures*

By George Granger Brown
Department of Chemical Engineering, University of Michigan

Four Methods for Computing the Temperature Developed by a Reaction—Graphical, by Trial, Algebraic and Slide Rule Methods Described

TO COMPUTE the temperature developed by a chemical reaction, such as the combustion of fuel or detonation of an explosive, the heat available o raise the temperature of the reaction products must qual the thermal capacity of the reaction products. ut as the specific heat varies with the temperature, hich is unknown, it is necessary either to estimate ie temperature for a tentative value of the specific eat and solve by trial, or to use an expression for the ean specific heat or thermal capacity as a function of ie temperature and solve the quadratic equation for mperature rise.

The various methods of estimating maximum temerature are best shown by demonstrations. Below are iven five different methods of arriving at this figure ith relative advantages indicated:

Graphical Method of Damour[1]

In his book Damour applies this method to find the mperature of combustion of a number of industrial els. For the present purpose it is sufficient simply o outline the method by a single application to find ie temperature of combustion in burning pure carbon ith the theoretical amount of cold dry air.

Damour uses a gram mol as a unit and assumes the ir to be composed of 4 gram mols of nitrogen to every ram mol of oxygen. This is equivalent to 80 per cent itrogen and 20 per cent oxygen by volume. It is not ecessary to use a gram mol as a unit; a pound mol, a ound, or a cubic foot might be used as well, provided ie equivalent values for heats of formation and ermal capacities or heat content are used. He repreents the reaction as follows:

$$C + O_2 + 4N_2 \rightarrow CO_2 + 4N_2 + 97{,}600$$

Estimating the final temperature as between 1,800 eg. C. and 2,200 deg. C., he computes the heat content f the products of combustion over this range as llows:

TABLE I—CALCULATED HEATS OF COMBUSTION

oducts of Combustion	Thermal Capacities, Cal. above 0 deg. C[2]. 1,800 deg. C.	2,000 deg. C.	2,200 deg. C.
O_2	27.2	31.8	36.6
N_2	56.8	64.2	71.6
Total	84.0	96.0	108.2

The total thermal capacities at the temperatures ken are plotted as indicated by points *a*, *b*, and *c* in ig. 1. A smooth curve (*abc*) is then drawn through ese points. As 97.6 Cal. from the reaction are vailable to raise the temperature of the gases, the final mperature will be that temperature at which the gases ill have a heat content of 97.6 Cal. and is indicated y the abscissa ($X_1 = 2{,}040$ deg. C.) of the intersection f the ordinate ($Y_1 = 97.6$) with the curve of thermal apacity.

This method requires an estimate of the final temperature and at least three computations of thermal capacities. However, if a number of computations are to be made upon the same reaction such a chart is very convenient, as the same chart serves for all calculations of the same reaction products.

Temperatures by Trial

If pure carbon is burned with 100 per cent excess cold air, the temperature of combustion may be found in the following manner, using more modern values than those given above.

We know that one gram mol of carbon burned to carbon dioxide liberates 97,200 cal. according to the reaction,

$$C + O_2 \rightarrow CO_2 + 97{,}200 \text{ cal.}$$
$$12 \quad 32 \quad 44$$

97,200 cal. per gram mol of carbon is equivalent to (97,200 × 1.8) B.t.u. per pound mol. As the molecular weight of carbon is 12, one pound of carbon burned to carbon dioxide according to the above reaction will liberate

$$\frac{97{,}200 \times 1.8}{12} \text{ or } 14{,}580 \text{ B.t.u.}$$

The above equation also indicates that 12 lb. of carbon requires 32 lb. of oxygen. Then 1 lb. of carbon will require 2.66 lb. or 31.44 cu.ft. of oxygen. 100 per cent excess air will then be 62.88 cu.ft. of oxygen and 236.4 cu.ft of nitrogen, assuming air to be 79 per cent nitrogen by volume

1 lb. C + 62.88 cu.ft. O_2 + 236.4 cu.ft. N_2 →
31.44 cu.ft. CO_2 + 31.44 cu.ft. O_2 +
236.4 cu.ft. N_2 + 14,580 B.t.u.

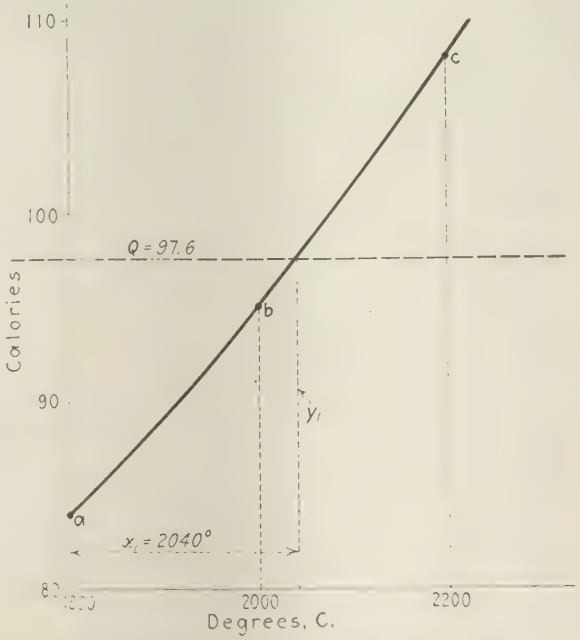


FIG. 1—THERMAL CAPACITY-TEMPERATURE CURVE

*This paper is a revision of one presented at the New York eeting of the American Chemical Society, September, 1921.

[1]Emilio Damour: "Le Chauffage Industriel et les fours a Gas," anslated by A. L. J. Queneau, "Industrial Furnaces and Methds of Control," *Eng. Mining J.*, 1906.

[2]Mallard and LeChatelier. *Ann. des mines* (8) 4 (1884), pp. 9 to 559.

If the air is supplied at 60 deg. F., the mean specific heats between 60 deg. F. and t deg. F. are used.[3]

Estimating 2500 deg. F. as the final temperature, the mean specific heat between 60 deg. F. and 2500 deg. F. of the products of combustion may be computed by multiplying the number of cubic feet of each gas by mean specific heat over the required range and adding. That is, (Total mean specific heat) $\times$ (degrees rise) = (heat content) = heat available.

TABLE II—CALCULATION OF MEAN SPECIFIC HEAT

Products of Combustion Gas	Cu.Ft.	Mean C_p[4] (60 to 2,500 deg. F.)	Mean Specific Heat
CO_2	31.44	0.0307	0.967
O_2	31.44	0.0191	0.601
N_2	236.40	0.0191	4.520

Total C_p (60 to 2,500 deg. F.) = 6.088.

Then total $C_p \times (t_2 - t_1)$ = heat available.

or $6.088\ (t_2 - 60) = 14580.$

$(t_2 - 60) = 2400.$

Therefore $t_2 = 2400 + 60$ or 2460 deg. F. which is a satisfactory check with the estimated 2500 deg. F.

The final temperature as calculated must check the temperature estimated for determining the specific heat. Usually a satisfactory check can be obtained in two trials.

This method is satisfactory, providing a table of mean specific heats over the particular range desired is available. Otherwise it becomes necessary to reduce the computations to the datum plane of the initial temperature of the available table and the method loses its advantage.

Algebraic Solution

A method of wide application uses an expression for the mean specific heat in which the temperature occurs as a variable. This leads to a quadratic equation which is solved for the variable—the temperature rise.

This method may be applied to the same computation as above, the combustion of carbon with 100 per cent excess air, using the expression for the mean specific heat instead of a numerical value from the tables. If the mean specific heat is multiplied by the temperature rise, in this case t, the expression for the thermal capacity is obtained, which may be used directly as indicated below.

As above

1 lb. C + 62.88 cu.ft. O_2 + 236.4 cu.ft. N_2 →
31.44 cu.ft. CO_2 + 31.44 cu.ft. O_2 +
236.4 cu.ft. N_2 + 14580 B.t.u.

TABLE III—CALCULATION OF THERMAL CAPACITY

Products of Combustion Gas	Cu.Ft.	Thermal Capacities[5] (0 deg. to t deg. F.)
CO_2	31.44	$(0.0227t + 0.385t^2\ 10^{-5})$
O_2	31.44	$(0.01786t + 0.883t^2\ 10^{-6})$
N_2	236.4t	$(0.01786t + 0.883t^2\ 10^{-6})$

Total thermal capacity = $5.694t + 0.357t^2\ 10^{-3}$

The thermal capacity must equal the heat available to raise temperature.

Heat content = $14580 = 5.694t + 0.000357t^2$.

[4] Mean specific of one cu.ft. of gas measured at 60 deg. F. and 30 in. mercury calculated from equations of Holborn and Henning, *Ann. Physik*, 22, 1907. Über die spez fische Wärme von Stickstoff, Kohlensäure und Wasserdampf bis 1,400 deg. C.

[5] Calculated from values of A. Langen. Mitteilungen über Forschungsarbeiten auf dem Gebiet des Ingenieurwesen Heft 8, S. 8. Berlin, J. Springer, 1908.

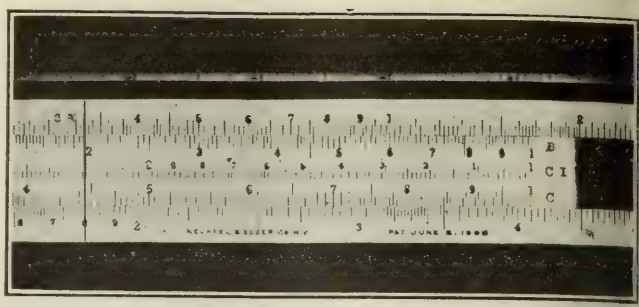

FIG. 2—SLIDE RULE SOLUTION OF QUADRATIC
$t^2 + 15950t - 40{,}890{,}000 = 0$

$$0.000357t^2 + 5.694t - 14580 = 0$$

$$t = \frac{-5.694 + \sqrt{(5.694)^2 + (4 \times 14580 \times 0.000357)}}{2 \times 0.000357}$$

t = 2250 deg. F.

This differs from the solution above, as Langen's values for the specific heat above 0 deg. F. were used instead of Holburn and Henning's above 60 deg. F.

Slide Rule Solution

The quadratic equation obtained above

$$0.000357t^2 + 5.694t - 14580 = 0$$

may be easily reduced to

$$t^2 + 15950t - 40{,}890{,}000 = 0$$

by dividing the equation by the coefficient of t^2. In this form it may be conveniently factored into

$$(t - 2250)\ (t + 18200) = 0$$

on the slide rule, using the CI and D scales, as shown in Fig. 2; 11 on CI being set over the constant term (40,890,000) on D, the product of any coinciding numbers on scales CI and D must equal 40,890,000. The hair glass is adjusted so that the difference between the corresponding values on CI and D equals the value of the coefficient of the t term (15,950). Thus 18,200 — 2,250 = 15,950. The two values so determined, with their signs changed, are the roots of the equation:

$$t = 2{,}250 \text{ or } -18{,}200.$$

Obviously, the positive value only is of interest, so the final temperature is 2250 deg. F. This method is convenient and can be executed rapidly and accurately with a little practice.

Graphical Solution of Quadratic

The same quadratic equation

$$t^2 + 15950t - 40{,}890{,}000 = 0$$

may be very conveniently solved for the positive root by the chart shown in Fig. 3. The constant term (— 40,890,000) is taken along the ordinates and the coefficient of t (15,950) is taken along the abscissas. The intersection of the indicated abscissa and ordinate is on the temperature line corresponding to the solution of the equation in this case midway between 2200 and 2300 or 2250 deg. F. Such a chart is very easy to construct, being made up entirely of straight lines, and may be used for any and all substances or mixtures in any units, English, metric, or otherwise.

The accuracy of any such calculation is limited by the accuracy of the specific heats used. For industrial work the following expressions derived from the work of Pier[6], Bjerrum[7] and Siegel[8] are accurate and very satisfactory.

[6] M. Pier, *Z. Elektrochem.*, vol. 15 (1909), p. 536; vol. 16, p. 517 (1910).

[7] Niels Bjerrum, *Z. Elektrochem.*, vol. 17, p. 731 (1911) and vol. 18 (1912). *Zeit. für Physikalische Chemie*, vol. 79, pp. 513, 537 (1912).

[8] Wilhelm Siegel, *Z. physik. Chem.*, vol. 87, p. 641 (1914).

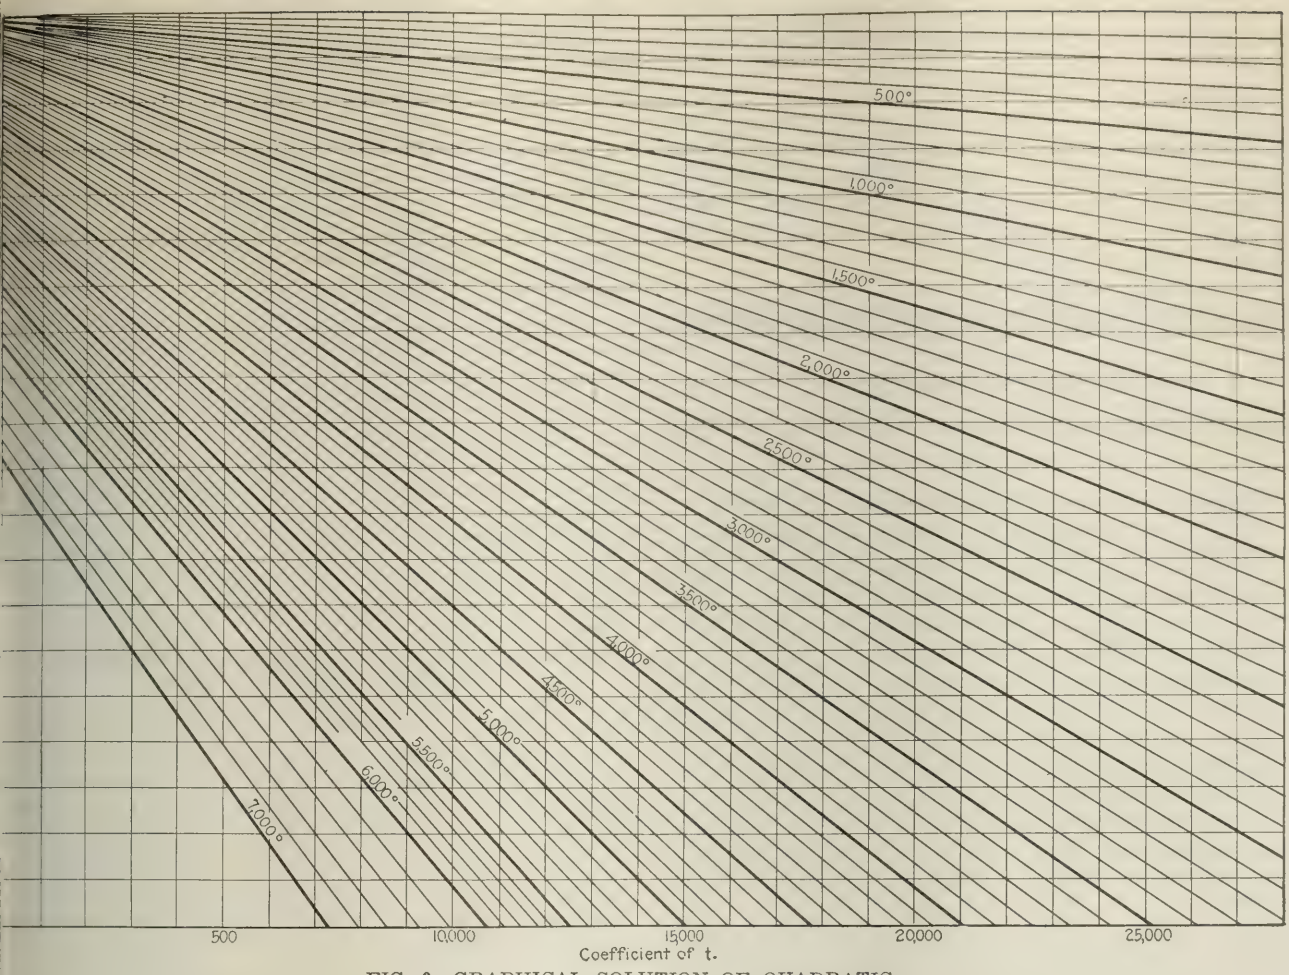

FIG. 3—GRAPHICAL SOLUTION OF QUADRATIC

MEAN C_p (0 TO t DEG. C.) IN CAL. PER GRAM MOL

Diatomic gases (N_2, O_2, CO) $= 6.9 + 0.00042t$.
CO_2 (up to 1250 deg. C.) $= 8.8 + 0.0024t$.
CO_2 (above 1250 deg. C.) $= 10.02 + 0.00072t$.
H_2O $= 7.8 + 0.00175t$.

EAN C_p (0 TO t DEG. F.) IN B.T.U. PER POUND MOL

Diatomic $= 6.88 + 0.000234t$.
CO_2 (up to 2300 deg. F.) $= 8.7 + 0.00135t$.
CO_2 (above 2300 deg. F.) $= 10 + 0.0004t$.
H_2O $= 7.75 + 0.001t$.

MEAN C_p [t TO $(t + x)$ DEG. C.] IN CAL. PER GRAM MOL

Diatomic gases $= 6.9 + 0.00084t + 0.00042x$.
O_2 (up to 1250 deg. C.) $= 8.8 + 0.0048t + 0.0024x$.
O_2 (above 1250 deg. C.) $= 10.02 + 0.00144t + 0.00072x$.
O $= 7.8 + 0.0035t + 0.00175x$.

MEAN C_p [t TO $(t + x)$ DEG. F.] IN B.T.U. PER POUND MOL

Diatomic gases $= 6.88 + 0.000468t + 0.000234x$.
O_2 (up to 2300 deg. F.) $= 8.7 + 0.0027t + 0.00135x$.
O_2 (above 2300 deg. F.) $= 10 + 0.0008t + 0.0004x$.
O $= 7.75 + 0.002t + 0.001x$.

Any of the expressions given above may be converted mean C_v over the same temperature range by subcting 1.985, or more simply 2, from the constant term. To convert from cal. per gram mol to cal. per gram, or m B.t.u. per pound mol to B.t.u. per pound, divide the tire expression by the molecular weight of the gas.

The above equations for calories per gram mol may be converted to calories per liter, or Calories (kilogram cal.) per cubic meter at 0 deg. C. and 760 mm. by dividing the entire expression by 22.4. The equations for B.t.u. per pound mol may be converted to B.t.u. per cubic foot at 60 deg. F. and 30 in. by dividing the entire expression by 378.

In every case, the thermal capacity or heat content of a gas over a temperature range is equal to the mean specific heat of the gas over that temperature range multiplied by the number of degrees in the temperature range. For example, the heat content of a pound mol of water vapor at constant pressure (C_p) between 1,000 and 3,000 deg. F.:

C_p [t to $(t + x)$ deg. F.] $= 7.75 + 0.002t + 0.001x$

Heat content $= 7.75x + 0.002tx + 0.001x^2$

Heat content (1000 to 3000 deg. F.)
$= 7.75\ (2000) + 0.002\ (1000)\ (2000) + 0.001\ (2000)^2$
$= 2000\ (7.75 + 2 + 2)$

Heat content, or thermal capacity at constant pressure (1000 to 3000 deg. F.) $= 2000 \times 11.75 =$ 23500 B.t.u.

Similarly the heat content between 1000 and (1000 + x) deg. F. may be computed for water vapor per pound mol from the following:

C_p [1000 to (1000 + x) deg. F.] $= 7.75 + 2 + 0.001x$

Heat content $= 9.75x + 0.001x^2$

where x is degrees rise above t deg. F. and may be determined graphically as outlined above by placing this expression for thermal capacity equal to the number

of B.t.u. available to raise the temperature and solving the quadratic equation for the positive root of x.

Summary

All of the methods given have been tried thoroughly. The last two procedures have been found for general work the most rapid and accurate methods, and no close estimate of the final temperature is required. Under the special conditions outlined, however, the first two procedures may be preferable.

Legal Notes

By Wellington Gustin

Duty of Seller and Shipper to Ship at Lowest Freight Rates—Court Reverses Itself

A dispute over the shipping of creosote resulted in an action brought by the F. J. Lewis Manufacturing Co. against the American Creosote Works, Inc., and decided by the Supreme Court of Louisiana. Plaintiff sued for $3,399.25, balance due on an oral contract in excess of $16,000, for 10 cars of creosote oil. Defendant set up a counter-claim in the amount of $3,361.68, as damages caused by shipping the 10 carloads of creosote over the Illinois Central R.R. at a cost of 50c. per 100 lb., when by proper attention and care, it was alleged, the oil might have been shipped over the New Orleans & Northeastern R.R. at a cost of 8c. per 100 lb. (90 Southern, 566.)

Both parties had offices or representatives in New Orleans, La., while plaintiff has a plant at Southport, La., and defendant's plant is at Louisville, Miss. The parties had been doing business together for some time, while plaintiff had a tank at Chalmette, just below New Orleans, and the creosote had been sent over the N. O. & N. R.R., to Louisville, Miss., at a rate of 8c. per 100 lb. from Chalmette. But it abandoned this tank at Chalmette and established a plant in Southport, which also adjoins New Orleans. These three points are in what is called the "New Orleans district." There was some confusion in the evidence as to where the creosote was to be shipped from.

It was shown that the custom of the trade was for the seller to do the shipping, and in this case the shipping was attended to by the plaintiff selling company.

Point of Shipment Uncertain

Plaintiff claimed that the creosote was to be delivered f.o.b. Southport, while defendant claimed that it was to have been delivered f.o.b. Chalmette. Correspondence and the evidence made the point of shipment uncertain, but the Supreme Court on the first appeal held the point to be New Orleans. Further, it held that the plaintiff was negligent in not looking up the published railroad freight rates and shipping to defendant over the best route at the best rates. It said the plaintiff could not select the road which made the greater charge at the expense of defendant whom it was pretending to serve, but that it must bear the loss for this failure and negligence in the part of its manager. Therefore judgment was given for the excess freight rate paid.

However, on a rehearing granted in this case the court found that a certain letter and correspondence showed the purchase was f.o.b. Southport, La., as the creosote, about 250,000 gal., was then in storage at this point and plaintiff no longer had or kept oil at Chalmette, having ceased doing business there before this transaction. Defendant in one letter confirmed sale of oil f.o.b. Southport to be shipped direct to Louisville, Miss. The court, in reversing its former decision, says the defendant was not in a position to claim a freight rate of 8c. per 100 lb. on this oil because the rate from Chalmette to Louisville used to be 8c. per 100 lb., in former dealings between the parties.

Further, there was no evidence to show what the rate was from Chalmette to Louisville at the dates of the shipments in question and there was no evidence to prove that the rate from Southport to Louisville via the Illinois Central was any different from that from Chalmette to the same destination via the New Orleans & Northeastern R.R., when these shipments were made.

Therefore the court reversed its former judgment and entered judgment for plaintiff for the amount due on the account for creosote and disallowed the counter-claim for excessive freight paid by defendant.

Natural Right in Secret Process Independent of Statutory Right in Patent

The United States Circuit Court of Appeals has stated the proposition as law, that the common law right of an inventor to the exclusive benefit of his invention so long as he can keep it secret from competitors is a separate and independent right from his statutory right under the patent laws to exclude others from its use for a limited term in return for the full disclosure of his invention to the public. This in the suit by the Nye Tool & Machine Works against the Crown Dies & Tool Co. (276 Fed., 377.)

In an advisory way, the court says that an inventor is not compelled by law to apply for and take out a patent. If he has produced a new composition of matter of such a nature that the ingredients and the process are safe from discovery by others either by observing his use of his invention or by independent investigation and experiment, he would have a much more enduring monopoly by refusing to make the "full disclosure" that our patent statute invites. Such is his natural or common law right. One seeks a patent only when he fears others may discover his invention and exercise their common law right to copy and use the same. So, as the court points out, the common law right and statutory right are separate and independent, neither infringing upon the other. Whether an inventor exercises or refuses to exercise his natural or common law right has nothing to do with his assertion of his statutory right, which consists exclusively of his power, through the courts, to restrain others from practicing his invention and to call them to account for having done so in defiance of his monopoly granted by the patent statute. This view of our patent system has been established in Supreme Court opinions. (97 U. S., 501; 210 U. S., 405.)

From another angle in this case the defendant contended that a patent could be assigned only as an entirety. But section 4898 of the U. S. Revised Statutes says that "any patent, or any interest therein, shall be assignable in law by an instrument in writing." The court said that the words "any interest therein" gives the patentee the right to subdivide and deed or lease his property as he pleases.

Notes on Aluminum Alloys for Casting*

Useful Foundry Alloys Contain Relatively Low Percentages of Copper, Zinc or Both — Other Metals Are Alloyed in Smaller Percentages—Physical Properties of Aluminum Alloys Used in America and Other Common Metals and Alloys Are Tabulated

THE two principal alloying ingredients of aluminum casting alloys at the present time are copper and zinc, usually taking the form of aluminum-copper or aluminum-zinc-copper alloys. Manganese and magnesium are frequently used. Nickel, chromium, tin and other metals have been alloyed with aluminum with varying degrees of success.

When commercially pure aluminum is alloyed with one or more of the common metals, the usual effects are an increase in the tensile strength and hardness, a reduction in the shrinkage and an improvement in the machining qualities of the metal.

Increased tensile strength and hardness are not always accompanied by a decrease in the elongation. However, there is usually a decrease in elongation when the increase in strength and hardness is caused by a change in the chemical composition of the alloy; but any change in the casting conditions which increase the tensile strength of an alloy also increases the elongation; hence there is a double gain of tensile strength and ductility.

What is true of alloying aluminum with small quantities of other metals is also generally true when other metals are alloyed with small amounts of aluminum. When this is done the good effects, as in the previous case, at first predominate, but the tendency for the ductility to decrease is present and it increases as the amount of aluminum increases.

Aluminum-Copper Alloys

All the useful alloys of the aluminum-copper series may be placed in one or the other of the two classes: Those containing less than 15 per cent copper, and those containing less than 11 per cent aluminum. The first class embraces the alloys most applicable to general casting purposes in the aluminum industry. Because of the nature of their constituents, alloys of this class are not subject to burning in the foundry, as are alloys containing more volatile metals.

The copper content in this series of alloys is now fairly well standardized. After years of experimentation and commercial practice in which almost every combination of aluminum and copper has been tried, trade sentiment has gradually crystallized in favor of an alloy containing from 7.0 to 8.5 per cent copper. This amount of copper produces a tough alloy the tensile strength of which will vary from 15,000 to 20,000 lb. per square inch, depending upon the casting conditions. It casts well and gives little trouble from checking and drawing of the casting, and is the one most generally used for all-round aluminum casting work. It is commonly known as No. 12 Alloy and will be discussed in detail later.

Alloys containing a higher copper content than this are sometimes used in the United States for castings which are to be subjected to high temperatures, water or steam pressure. A high-copper alloy is frequently used in the die-casting industry because of its relatively low shrinkage. Castings made from such alloys may fail if subjected to repeated shocks and stresses.

Alloys of the second class, containing less than 11 per cent aluminum, are known as aluminum bronzes. The aluminum content usually ranges from 1 to 10 per cent, that containing 10 per cent aluminum probably being most popular. A greater amount makes the metal hard and brittle, for the effect of aluminum is very similar to that of copper in the light alloys of aluminum. The tensile strength of aluminum bronzes is high, and ranges from 80,000 to 110,000 lb. per square inch. These bronzes do not corrode readily, and have a great resistance to alternating stresses, being superior to some steels in this respect.

Intermediate alloys of the aluminum-copper series, ranging from 15 to 90 per cent of copper, give crystalline and brittle grayish-white alloys of no use. After about 80 per cent of copper is reached the red color of the copper begins to show.

Aluminum-Zinc Alloys

The useful alloys of the aluminum-zinc series may, like those of aluminum and copper, be divided into two classes: Those containing less than 33 per cent zinc, and those containing a relatively small amount of aluminum.

Zinc produces a very strong alloy with aluminum, the tensile strength running as high as 38,000 lb. per square inch for the alloy consisting of 50 per cent zinc and 50 per cent aluminum. Such an alloy, however, is excessively brittle. The decrease in ductility of these alloys as the zinc content increases places the maximum of zinc at 33 per cent, and even this is much too high if the casting is expected to withstand stresses. The best aluminum-zinc alloys usually possess considerably less zinc than this. Zinc tends to give additional fluidity to aluminum, and produces sharp and sound castings when skillfully cast.

For forging, few metals excel an alloy containing from 10 to 15 per cent zinc. This alloy is tough, flows well under the forging dies and produces a finished product which is solid, easily machined and remarkably strong per unit of area. Castings made from aluminum-zinc alloys machine well, and the machining qualities improve with aging of the metal.

Alloys of this class seem to be unusually sensitive to irregularities in the casting process. If the metal is overheated there is danger that the zinc may be burned out. In addition, these alloys are more subject to drawing in heavy parts or lugs than are the copper alloys. This tendency, however, can in most cases be overcome by proper gating, suitable chills and risers, and adequate temperature control. Zinc alloys are unusually sensitive to high temperatures, and therefore can-

*From sales department condensed data prepared by the Technical Department, Aluminum Company of America.

not be used where the casting will be subjected to considerable heat. A casting made from a 25 per cent zinc alloy when raised to a temperature of 100 deg. C. loses one-third of the tensile strength it possessed at 20 deg. C. Zinc alloys have never been very popular in the United States. Doubt in the minds of many as to their freedom from deterioration with age has probably had much to do with their limited use.

Alloys in the second class of the aluminum-zinc series, those composed of relatively small amounts of aluminum, are known as aluminized zinc. The aluminum content is usually 5 or 10 per cent. These alloys are used in zinc-galvanizing baths to make the bath more fluid and to clear it of oxides, and in the manufacture of aluminum brass, but they are never used directly as are the aluminum-zinc casting alloys.

Aluminum-Zinc-Copper a Favorite Alloy

As previously stated, an alloy of aluminum and zinc has never been very popular in the United States. Where zinc is used the trade favors the addition of small quantities of copper. Copper increases the tensile strength, improves the casting qualities and gives greater rigidity to the aluminum-zinc alloy. In England an alloy composed of 13 per cent zinc and 3 per cent copper is used quite extensively. In the United States an alloy containing 15 per cent zinc and 3 per cent copper finds most favor, and is known to the trade as No. 31 Alloy. These alloys, either with or without the addition of copper, have never been as popular in the United States as they are in Europe.

In general, manganese influences aluminum in much the same manner as copper, renders it first both harder and stronger but less ductile, and subsequently decreases the strength as well as the ductility. Manganese alloys are very resistent to corrosion, being superior to the pure aluminum in this respect, the resistance increasing with increase in the manganese content. These alloys are most frequently rolled into sheets, but as 1½ and 2 per cent manganese alloys are dense and close grained, they are not infrequently used for casting small parts, such as pipe fittings, which are to be subjected to water or steam pressure.

Alloys of magnesium with aluminum are usually known as magnalium. Because of the great affinity of magnesium for oxygen, these alloys tend to form considerable dross on remelting unless the magnesium content is low. As a result, it is not generally good practice to add more than 5 per cent magnesium. Most alloys possess even less than this amount, and few commercial alloys carry over 2 per cent magnesium.

Magnesium alloys are harder, stronger and lighter than pure aluminum. Their tensile strength is practically equal to that of No. 12 Alloy, and their elongation is greater. Magnesium tends to make the mixture more fluid at low temperatures.

Magnesium may be introduced in the following manner: The pure magnesium is held in a pair of iron tongs and pushed slowly to the bottom of the crucible after it has been removed from the fire, or in the ladle just before pouring. It must be stirred slowly until the magnesium has completely melted from the tongs as determined by the sense of touch. The magnesium should be added in small amounts. If a long stick is pushed into the crucible it may break and the broken pieces float to the surface, where they will catch fire before they are melted, taking oxygen from the air instead of from the aluminum or the dissolved gases. After sufficient magnesium has been added more vigorous stirring should be continued for a short time in order to give the oxide of magnesium a chance to float to the surface. Then it should be poured and skimmed in the usual way. No other flux is necessary. Care should be taken to see that the tongs and magnesium are dry, to eliminate violent action and danger in introducing the magnesium.

Other Alloys Less Useful

Nickel is sometimes used as a hardener for aluminum, and produces practically the same effect as copper. However, nickel costs more than copper, and it has been found very difficult to make the nickel-rich alloy for incorporating the nickel in the melts. The nickel content should never exceed 5 per cent, for a 5 per cent alloy develops practically the full tensile strength that can be obtained without decreasing the elongation to such an extent that the casting would be unsuitable for commercial foundry work.

Small proportions of tin are sometimes advantageously used with aluminum to give greater strength and rigidity to heavy castings as well as to reduce the shrinkage of the metal. Tin also serves to give sharpness to the outline of the casting. The tendency, however, to reduce the elongation to the point of impracticability prevents the general use of tin-aluminum alloys.

No casting alloys of any value are formed by alloying aluminum with iron. A small amount of iron always occurs in aluminum as an impurity, but is only detrimental when it exists in amounts exceeding 1.5 to 2.0 per cent. The effect of more than these percentages of iron is to dangerously reduce the elongation. It also makes the molten metal sluggish, necessitating a higher temperature in the furnace with the consequent tendency toward blow holes and shrinkage cracks in the finished casting.

TABLE I—DENSITIES OF METALS

(Data for aluminum from Research Bureau, A. C. O. A. Remainder of table compiled from Smithsonian physical tables and other sources. Values for 20 deg. C., 68 deg. F.)

	Grams Per Cubic Centimeter	Pounds Per Cubic Foot	Weights of equal Volumes With No. 12 Alloy = 1
Magnesium	1.75	109	0.612
Aluminum (Al, 99.7)	2.70	169	0.944
Aluminum (Al, 99.0)	2.71	169	.....
Aluminum (Al, 98.0)	2.73	170	.....
No. 12 Alloy (Al + Cu. 7.0 to 8.5)	2.84 to 2.87	177 to 179	1.00
No. 31 Alloy	3.0	187	1.05

Bronze, cast (Cu 80; Sn 20)	8.7	543	3.04
Nickel	8.8	549	3.08
Copper	8.9	556	3.11
Lead	11.3	705	3.95

Silicon in the ordinary casting alloys hardens the metal, reduces elongation and affects adversely the machining qualities when it occurs in too large quantities. Care should always be taken to keep the silicon content low, not exceeding 1.0 to 1.5 per cent.

The density of a metal is subject to variation from changes in both composition and structure. For this reason the values which are given in various books are frequently conflicting because the exact composition and structure are not stated. In general an attempt has been made in Table I to select values which are representative for the metals listed. In the case of aluminum and No. 12 alloy the values hold for dense castings. If the castings are somewhat porous they will have cor-

TABLE II—MODULI OF ELASTICITY

Metals	Lb. Per Sq.In.
Lead	2,500,000
Aluminum	9,000,000
No. 12 Alloy	10,000,000
Cast Iron (gray)	12,000,000 to 14,000,000
Soft steel	30,000,000

Invar steel	0.0000006	0.000001

respondingly lower densities, while if the impurities present are greater, the density may be increased somewhat.

The thermal conductivity of aluminum is relatively high and this property makes the use of aluminum particularly advantageous in the construction of water-jacket walls, oil-pans and other motor parts which it is desirable to keep cool. Table IV lists some of the metals in the order of their relative thermal conductivity.

It is important to know the thermal expansion of a metal when it is to be used for castings such as automobile pistons, which are subject to considerable variation in temperature. The linear thermal expansivity of aluminum is intermediate between that of zinc and brass or copper, and about twice that of iron and steel. Table V shows the linear thermal expansivity per degree for unit of length of various metals. The volume expansion coefficient may be taken as three times the linear expansion coefficient.

The shrinkage of a metal is the linear contraction in cooling from the melting point to room temperature and determines the allowance the patternmaker must use in order to obtain a finished casting of the correct size. The shrinkage of aluminum alloys is somewhat greater than that of cast iron but less than that of steel. (See Table VI.

The purest aluminum so far obtained melts at a temperature of 658.7 deg. C. or 1217.7 deg. F. as shown in Table VII. The commercial grades of metal melt at somewhat lower temperatures. Aluminum has the relatively high boiling point of about 1,800 deg. C. and is not appreciably volatile under ordinary conditions at temperatures below 1,000 deg. C. It is not good practice, however, in making castings of aluminum to heat the metal much above its melting point or to allow it to remain molten for a great length of time.

Alloys differ from pure metals in that they do not melt at constant temperature but over a certain temperature interval. Alloys of eutectic composition are an exception to this rule and melt at constant temperature. The eutectic or lowest melting alloy of the copper-aluminum series contains 32 per cent copper and melts at 540 deg. C. (1,004 deg. F.). No. 12 alloy contains 8 per cent copper; it begins to melt at 540 deg. C. and is completely molten at 636 deg. C. (1,177 deg. F.).

The specific heat of aluminum is 0.21 at room temperature. This means that the quantity of heat that would raise the temperature of a given weight of aluminum through one degree, would raise the temperature of the same weight of water through 0.21 of one degree. The specific heat of aluminum increases with rise of temperature and is about 15 per cent greater at 500 deg. C. The mean specific heat in the temperature interval, 20 to 100 deg. C., for a number of metals, is given in Table VIII.

TABLE VI—SHRINKAGES OF METALS
(Inches per foot)

Pure aluminum	0.21	Brass	0.19
No. 12 Alloy	0.18	Gray iron	0.12
No. 31 Alloy	0.18	Steel	0.25

TABLE VII—MELTING POINTS
(These are the values accepted by the Bureau of Standards and given in their Circular No. 35. They hold for samples of the highest obtainable purity; less pure samples will in general have a lower melting point.)

Metal	Degrees Centigrade	Degrees Fahrenheit
Aluminum	658.7	1,217.7
Magnesium	651	1,204
Copper	1,083.0	1,981.4
Manganese	1,230	2,246
Nickel	1,452	2,646
Silicon	1,420	2,588
Iron	1,530	2,786
Zinc	419.4	786.9
Lead	327.4	621.3
Tin	231.9	449.4

TABLE VIII—SPECIFIC HEAT
Mean Specific Heat, 20 to 100 deg. C. (68 to 212 deg. F.)
(Compiled mainly from Smithsonian Physical Tables)

Water	1.000	Zinc	0.093
Magnesium	0.248	Copper	0.093
Aluminum	0.216	Brass	0.09
Cast iron	0.12	Tin	0.055
Manganese	0.121	Lead	0.031
Nickel	0.109		

The electrical conductivity of pure aluminum is 61 per cent of that of copper. No. 12 alloy has an electrical conductivity only about 32 per cent of the conductivity of copper. Alloys have been developed which have conductivities less than 20 per cent of that of copper and which have temperature coefficients of resistivity less than half that of pure aluminum.

Strengthening Springs by Overstrain

It is a known experimental fact that if a metal is loaded somewhat beyond the limit of proportionality, the load then released and then retested, the limit of proportionality will be found at a higher stress than originally. However, it is not so well known that this obscure physical phenomenon has long been applied in industry.

In manufacturing helical springs, these are first of all coiled to a height considerably above their finished height, then hardened and tempered. Then they are compressed to the limit, which overstresses the metal beyond its yield point, and the spring acquires a slight permanent set, so that upon removal of the load the spring returns only as far as the designed height. This has always been done to lift the elastic limit, so as to have the advantage of the greater strength thus induced.

Temperature-Pressure Curves of Petroleum Products

By M. B. Cooke
Assistant Refinery Engineer, Bureau of Mines

In the course of investigations now in progress by the Bureau of Mines into the nature of "gum forming" constituents of gasoline, several gasolines and other petroleum products were heated in a small bomb and pressures of considerable magnitude were developed. As the bureau has received many inquiries for data showing the pressure that may be developed in a still when gasoline or other oil is subjected to elevated temperatures, it was thought advisable to record the pressures observed at various temperatures in the course of this work. These data were merely a byproduct of the main investigation.

Gasoline and similar products are very complex mixtures and it is difficult to determine accurately the true vapor pressures; hence the vapor pressures of the oils used in these tests have not been studied in detail, but the data obtained may be taken as representative of the pressure-temperature relations of the various oils in commercial work.

Apparatus and Procedure

The apparatus for the tests consisted of a small steel bomb designed to carry a working load of 1,000 lb. per sq.in. with a factor of safety of 20. This bomb was constructed from a hexagonal piece of steel bar, and the outside dimensions without the cover were about 2½x6 in. The lid was made in one piece from the same material, was ⅝ in. in thickness, and was threaded on the inside of the rim. The bomb proper had inside dimensions of 1½x5⅜ in. and was threaded on the outside of the rim. The lid was also provided with a male rim which fitted into a groove, containing a lead gasket, machined in the top of the bomb. A pressure gage mounted on a ¾x6-in. brass nipple of ¼-in. bore was screwed into a hole in the center of the lid. The total capacity of the bomb and gage connections was 160 c.c. The bomb was heated in a bath of steam cylinder oil which was stirred thoroughly.

The apparatus was tested by placing in it 100 c.c. of distilled water, closing the bomb, and heating it in the oil bath to a maximum temperature of 200 deg. C. At intervals during the test the temperature of the oil and the pressures developed in the bomb were simultaneously recorded. These results are given in Table I together with data taken from the work of Marks and Davis.[1]

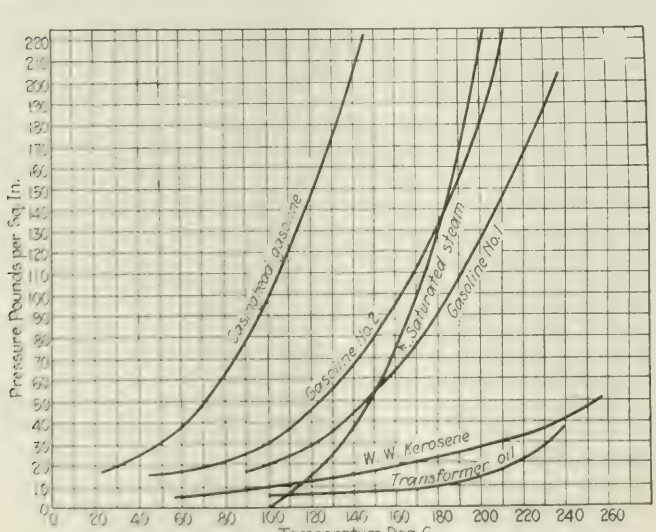

FIG. 1—TEMPERATURE-PRESSURE CURVES

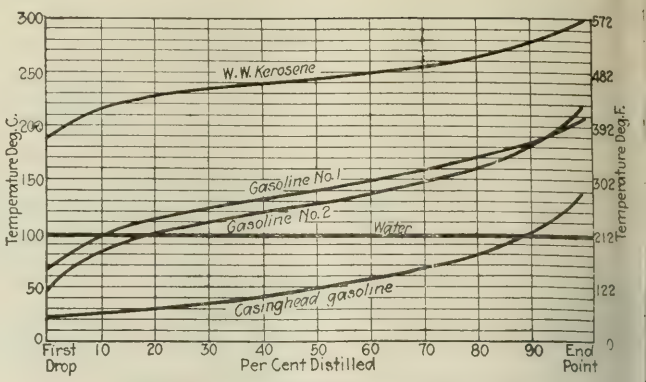

FIG. 2—DISTILLATION RANGE CURVES

TABLE I—COMPARISON OF PRESSURE EXERTED BY 100 c.c. WATER IN BOMB AND THEORETICAL PRESSURES

Temperature of Oil in Bath Deg. C.	Deg. F.	Pressure, Lb. Per Sq.In. (Gage)	Pressure, Saturated Steam (Marks and Davis Tables)
160.0	320.0	70	73
181.0	358.0	130	133
190.0	374.0	163	167
193.0	379.0	175	179
198.0	388.0	200	202

In comparing the results actually obtained in these experiments with data taken from the tables, it will be noted that the maximum error (probably due to the presence of air in the bomb) was 4 lb. per sq.in. It can be assumed therefore that the determinations on gasoline represent fairly closely the pressures that would be developed under theoretically perfect conditions.

Temperatures and pressures were recorded also as the bomb cooled down and showed that the lag between the oil bath and the bomb was probably not more than 1 deg. C.

Discussion of Data

One sample of casinghead gasoline, two of motor gasoline, one of kerosene, and one of transformer oil were heated in the bomb as described above and the resulting temperature-pressure curves for the various products are given in Fig. 1. The distillation range as determined by the standard A.S.T.M. method[2] is given in Fig. 2. The distillation range of transformer oil is not given because it is too high to obtain by the standard A.S.T.M. method.

It will be noted by referring to the curves in Fig. 1 that petroleum products with a low boiling range, such as casinghead gasoline and some of the lighter motor gasolines, generate a higher pressure at a given temperature than water vapor. Petroleum products with a relatively high boiling range, such as kerosene and transformer oil, generate less pressure than water vapor at a given temperature. In general, the pressure generated by petroleum products when subjected to elevated temperatures varies inversely with the average boiling point of the product. The temperature-pressure curves however, are not parallel, due to the varying composition of the products. For the same reason, the distillation range curves are not parallel.

Manufacture of Fireclay Refractories

Outline of Plant Operations at the Evens & Howard Fire Brick Co., St. Louis—Forming Brick and Special Shapes—Drying—Burning—Manufacturing Operations Co-ordinated to Obtain Maximum Production Efficiency

By Alan G. Wikoff

ST. LOUIS has long been an important center of the fireclay refractory industry because of the exceptional quality of the plastic fireclay in the famous Cheltenham seam underlying the city and county of St. Louis. This clay is refractory enough for many industrial purposes, but the increasing use of very high temperatures has created a demand for more highly refractory products, which has been met by the addition of non-plastic flint clay. Fortunately deposits of excellent flint clay are abundant in the east-central portion of Missouri. But the present plants are no longer able to obtain their entire raw material supply right at their doors, as was the case in the earlier days. Manufacturing methods have also kept pace with the development in service requirements for refractories so that the modern plants make full use of such factors as scientific control and material-handling equipment in obtaining efficient production.

Plant Layout for Straight-Line Flow

Situated in the rolling country just west of St. Louis is the modern firebrick plant of the Evens & Howard Fire Brick Co. The straight line flow from storage pile to stock shed and loading platform is evident from the layout as shown in Fig. 1. The spur from the St. Louis Belt & Terminal R.R. which passes the boiler house, clay shed and calcine kiln is an elevated or high line so that hopper-bottom cars can be dumped directly from it. The clay products are formed and dried in the large 4-story brick building connecting with the clay shed, burned in the kilns which are numbered as shown and then transferred to the stock shed or directly to cars.

As a brick 9x4½x2½ in. is the standard size, plant capacities in this industry are often stated in terms of 9-in. brick, other sizes and shapes being calculated to their equivalents in 9-in. brick. On this basis the daily capacity of this plant is about 115,000 9-in. equivalents, or, roughly, 400 tons, since a 9-in. brick weighs 7 lb.

Raw Materials

As has been indicated, two types of clay form the primary raw materials—Cheltenham plastic fireclay and flint clay.

At the present time the Cheltenham clay is obtained from mines owned by the company, about 5 miles north of the plant. Here the clay occurs as a 10-ft. vein about 100 ft. under ground. A shaft is sunk to the proper level and galleries are run into the vein of clay. Fig. 2 is a general view of one of the galleries. At Mine No. 6, which has just been opened, the clay

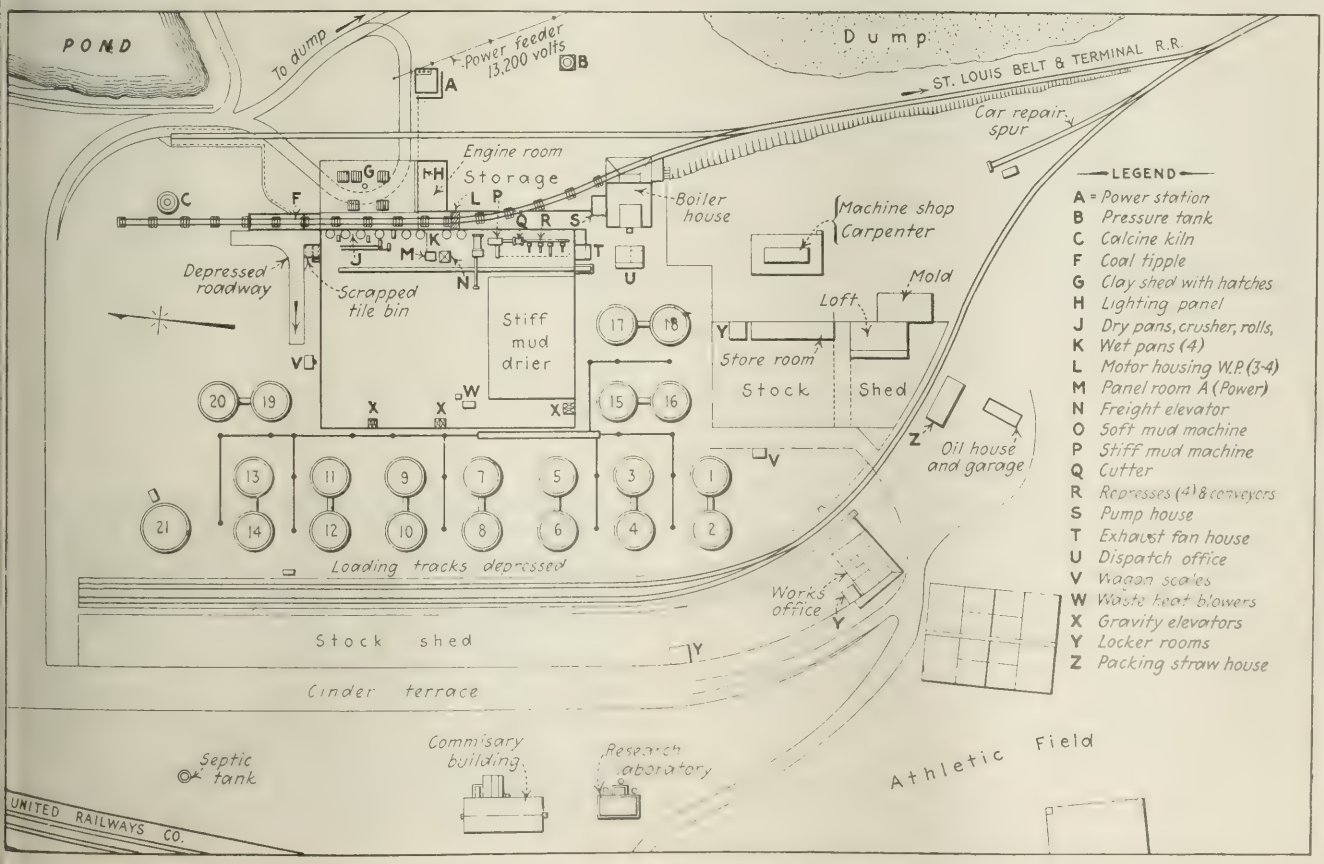

FIG. 1—LAYOUT OF FIREBRICK PLANT

FIG. 2—GALLERY IN A CLAY MINE

loosened by blasting and by pick is loaded upon cars which are hauled to the shaft by a mule, raised by an electric hoist and dumped into elevated storage bins. As yet this mine has not been placed upon a production basis, but it is expected to yield 250 tons a day. The clay from these mines fuses at about Seger cone 31, which is equivalent to 1,750 deg. C., or 3,182 deg. F.

For transporting clay, the company has its own standard-gage hopper-bottom cars.

Flint clay of a grade known as No. 1 white flint is brought from Owensville, Mo., and vicinity, about 100 miles west of St. Louis, where it occurs in pockets in sandstone varying from 100 to 250 ft. in diameter and from 20 to 75 ft. thick. Owing to the fact that the clay has to be hauled from 1 to 5 miles with teams, shipments depend upon fair weather and accordingly it is necessary to provide storage facilities at the plant. If the clay is not used as received it is transferred from cars on the high line to storage piles by an Ohio locomotive crane, which also serves to load hopper-bottom cars when material in storage is to be used.

Grinding Cheltenham and Flint Clays

When ready to be ground, the clay is dumped from hopper-bottom cars on the high line, as shown in Fig. 3, into hoppers which discharge by means of plate feeders into dry pans, *J*, Fig. 1. Each of the three Frost dry pans is provided with a bucket elevator to carry the ground material to the upper floor of the building, where it is screened over sloping screens into master storage bins. Flint clay and Cheltenham clay are ground and stored separately.

Grog and Calcine

In addition to the raw clays just described, there are three materials derived from them, but differing in physical properties, which may be termed secondary raw materials. These are plastic clay grog, flint clay grog and flint clay calcine. Grog is a general term applied to material which has been reground after having been burned. Thus broken or imperfect plastic clay brick taken from the kiln might be ground up to form plastic clay grog. Flint clay calcine is prepared by burning the clay in lump form without preliminary grinding in a vertical shaft kiln located alongside the outer end of the high line so that it can be charged directly from the cars.

Grogs and calcine are ground separately in an Austin gyratory crusher, screened and stored in master bins similar to those used for the raw clays.

There are thus five materials which may be used in a variety of combinations according to the properties desired in the finished product. About twenty-five standard mixes are regularly employed at this plant in the production of a wide range of refractories.

Having the five ground materials in separate bins makes the preparation of any desired mix an extremely simple matter. Freese feeders in the bottom of each master bin are so calibrated that a constant, predetermined flow of material can be delivered from any number of the bins onto a common belt conveyor which runs along one side of the bins. A bucket elevator and another belt conveyor serve to place the mixture thus formed in bins located directly over the machines which are to temper the clay with water. With this arrangement, the proportions of a mixture can be controlled automatically to within 1 per cent.

Methods of Forming Fireclay Refractories

Fireclay refractories may be formed in any one of several ways. Brick may be made on machines or in hand presses. According to the consistency of the mixture (which depends upon the amount of water present), the process is referred to as soft mud, stiff mud, or dry press. In the dry press process, water is added merely to dampen the clay, when the amount normally present in the clay is not sufficient. All three processes are used at this plant, the proportions being about 20,000 hand press, 20,000 dry press, 60,000 stiff mud and 15,000 hand molded.

Many of refractory shapes are so large or so complicated that they must be molded by hand. As the manufacturing operations in the hand-molding and machine departments differ to quite an extent, they will be treated separately.

Machine-Made Firebrick

Clay mixtures for use on the brick machines are mixed with water to the proper consistency in an American pug mill, which consists essentially of a number of blades mounted on a horizontal shaft rotating in a steel trough. The blades are set so that the clay gradually moves toward the discharge opening which feeds an American auger machine (*P*, Fig. 1). Here the clay is forced through a rectangular die emerging in the form of a dense, continuous column about 9 in. wide and 4½ in. thick. As it moves along on a small belt conveyor it is picked up by the Freese cutter, *Q*, where a number of tightly stretched wires pass vertically through the clay column forming about twenty-five brick at a cut. The movement of the clay is not interrupted during the cutting process. The brick pass on a belt conveyor in front of three Bonnot represses. (The fourth press shown at *R*, Fig. 1, is being installed.) At each of

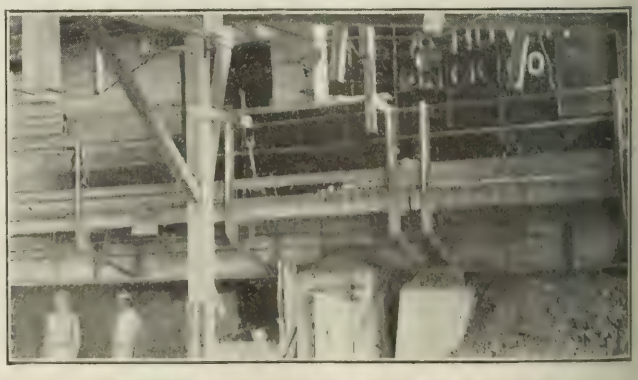

FIG. 3—FEEDING CLAY TO DRY PANS

these, an attendant removes two brick at a time from the conveyor and places them in the press. This operation assures smooth sides and sharp, straight edges so that the brick are easily laid up. Brick made in this way are known as wire side-cut, repressed. This machine has a capacity of 60,000 9-in. equivalents.

Waste Heat Driers

As they come from the presses, the brick are stacked on double deck cars with galvanized truck frames. They are spaced with some degree of regularity so that drying will be as uniform as possible. Waste heat from the kilns which are cooling is supplied to a parallel row of tunnel driers by means of a powerful blower. A transfer car running on a track along the front of the driers makes it possible to place the cars of green brick in any one of the driers. The cars are pulled through by a steel cable attached to an electric winch, three cars of dried brick being drawn at a time. The waste heat driers were installed by the L. E. Rodgers Engineering Co., Chicago.

Since there is always the possibility of not having sufficient kilns cooling at a given time to maintain the proper temperature in the driers, an auxiliary furnace is provided to take care of such emergencies, but this has never been required to date.

All products being burned in the same type of kiln, the general subject of burning will be considered after discussing briefly the production of hand-made ware.

Preparing Clay for Hand-Made Ware

Instead of being put through a pug mill, all clay for hand-made ware is tempered with water in a wet mill. There are four 9-ft. Frost wet pans, *K*, with 14-in. mullers, so arranged under the storage bins that each pan is served by two bins. The pans are elevated so that mud carts can be run underneath to receive the clay as discharged by a Wynn unloader. The mud carts distribute the clay to the molding gangs on the upper floors of the building.

Hand-Made Brick

Each hand-press for making brick is operated by a gang of four men. A wad of clay somewhat larger than the brick to be made is worked into a shape approximately that of the mold and is then thrown with considerable force and skill so as to fill the mold completely and uniformly. After the excess clay has been removed, the press is operated by hand and the brick removed ready for drying. This process is used for the more refractory grades of firebrick, and the five hand presses (made by George Carnell, Philadelphia) have a daily capacity of about 20,000 9-in. equivalents.

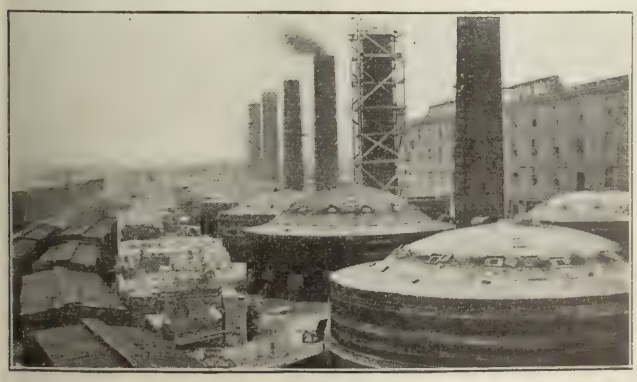

FIG. 4—GENERAL VIEW OF KILN YARD

FIG. 5—NORTH END OF KILN YARD

Although the standard brick with its modifications, such as key, wedge, neck, arch, skew and circle, is applicable in a wide range of refractory construction, there are many cases where more satisfactory results can be obtained by the use of special shapes. Many of these are very complicated and their successful manufacture calls for great ingenuity, skill and experience.

Wooden molds are used wherever possible, although some of the larger pieces are built up patiently by hand. Having dusted the mold with fine sand so that the clay will not stick, the molder throws in a lump of clay. After working this uniformly into all parts of the mold, the excess is removed by passing a tightly stretched wire across the free surface of the mold and the piece is carefully removed from the mold and placed upon the floor to dry. The time the ware must remain on the drying floor depends upon the size and shape of the pieces and is determined largely by experience.

By far the larger part of the floor space of the main building is required for the drying floors, as the nine tile gangs (two men each) produce about 15,000 9-in. equivalents per day.

Burning

All ware is burned in round, down-draft periodic kilns, there being twenty 36-ft. kilns each capable of holding 70,000 9-in. equivalents and one 40-ft. kiln with a capacity of 130,000 9-in. equivalents. Figs. 4 and 5 are general views of the kiln yard. A system of tracks makes it possible to bring the cars of brick directly from the driers to the kilns. A loaded car en route to the kiln may be seen in the lower part of Fig. 5. Hand ware is loaded onto two-wheel spring carts, lowered to the yard level by gravity elevators.

Setting the ware in the kiln is an operation which calls for a great deal of experience. Since practically all of the special shapes are incapable of supporting other brick and tile owing to their peculiar shape, the lower half of the kiln is set with brick, arranged according to a definite plan so that the heat will be distributed as uniformly as possible throughout the setting. The careful arrangement is evident in Fig. 6, which shows a kiln being drawn. The upper part of the kiln is filled with special shapes. Heat from the sixteen fireboxes set in the circumference of the kiln rises inside following the crown and then passes down through the ware and the flues in the kiln bottom to the stack.

The kilns are fired on a definite schedule according to the ware in them. Instruction sheets are prepared each day covering every kiln on fire that day. All kilns have pyrometers, and Seger cones and trial pieces are used to determine the finishing time. During the cooling period, the flue dampers are set so that the heat

goes to the driers instead of up the stack. Spring wheelbarrows holding about seventy brick are used to draw the kilns.

An accurate record is kept of the performance of each kiln, all ware being checked in and out and the results entered along with such data as the temperature schedule, hours burned, coal consumption, etc.

About 16 days are required for the complete cycle of setting, burning, cooling and drawing. The average burning time is 180 hours, while setting and drawing each require about 1½ days with a gang of twelve men.

Fuel and Power

Coal, ordered in hopper-bottom cars, is dumped directly from the high line into a tipple holding 150 tons, from which it is distributed around the yard to the kilns by means of an Autocar truck. Steam for heating the drying floors when necessary is supplied by the boiler house.

Power throughout the plant is electrical, machines being equipped with individual motor drive.

Research Laboratory

The laboratory is equipped to make all standard tests for refractory wares, having a muffle kiln, load furnace and high-temperature furnace in addition to the necessary chemical apparatus. Fig. 7 shows the furnace room, with a glimpse of the laboratory beyond. All clays and finished products are checked up at least once a month, but the most important part of the laboratory work is the development of new products in co-operation with the factory and sales department.

New clays are thoroughly tested before use. The fusion test is, of course, the most important guide to the refractory qualities of the clay, but chemical analysis and load tests are also of value. The regular supply of clay from deposits whose properties have already been determined is inspected at the mine, the flint clay as it is being loaded, and the soft clay by the top level boss.

Functions of Planning Department

Perfect co-ordination of all manufacturing operations is essential if waste of time and materials is to be eliminated in filling orders. Consider, for example, an order for several varieties of special shapes, some small and simple, others large and complicated, all to be delivered at the same time. In such a case, handling would be minimized if all pieces were burned in the same kiln and transferred directly to the freight car. But if the different shapes were manufactured simultaneously, it is obvious that the smaller pieces would be dry before the larger ones and that consequently valuable drying floor space would be wasted.

It is the function of the planning department so to schedule the operations that such wastes are eliminated. This requires an accurate knowledge of the capabilities and limitations of each department and the characteristics of each type of ware. Furthermore, with such data at hand, it becomes possible to promise delivery intelligently. Accordingly, it may be of interest to outline briefly the methods followed in this work.

Analysis of Orders

Orders naturally vary greatly in complexity, from those which call simply for material in stock to those covering a variety of special shapes. If the material is in stock in sufficient quantity the order goes directly to the shipping clerk. If special, it may be of a type which has been made before, in which case the molds will be in stock, or it may be necessary to make new molds. These points having been determined, it is possible to set a delivery date from a knowledge of the standard time required to make, dry and burn that particular type of ware and also of the amount of work already scheduled.

FIG. 6—DRAWING A KILN

Planning of Making

An order card is made out covering the whole order and separate route cards are made out for each class of ware on the order. This makes it possible to fix the dates for making the different kinds of ware so that all of the order will be ready for setting at the same time. The order card acts as a check to prevent any of the items being overlooked.

When the molds are ready, a molder's order is made out. This gives the making date, the exact amount (including a certain overage to cover possible losses) of war to be made, and the location on the drying floor which experience indicates as the best place for drying that type of ware. When the molding is completed the location on floor is noted on the route card, and an entry made on the order card showing ware made and number of making hours.

Setting

In planning the setting of ware, the kilns are considered as divided into four horizontal zones, the lowest zone being called the first. Experience has shown what zone is best adapted to each type of ware. Thus, some shapes can be set only in the top of the kiln or fourth zone.

All this is considered in preparing the setting schedule, which shows the ware to be set by zones and its location on the drying floor. A kiln near the ware and also convenient to the storage or shipping point should be available if the planning has been carefully done. In addition, the setting of the various kilns should be timed to give as uniform heat as possible to the driers and to prevent loss of time in kiln turnover.

Drawing and Shipping

On the date planned for drawing, the necessary cars are placed as near to the kiln as possible by the yard foreman. From the drawing report, an entry is made on the route cars showing amount drawn and lost. From the shipping ticket, a record of the amount shipped is made on the route cards and if the order is filled, the order card and route card are filed as completed.

FIG. 7—RESEARCH LABORATORY

Careful inspection at all stages is of vital importance. The thoroughness is indicated in the following brief summary.

All new molds are inspected when completed (and stock molds before using) by the mold inspector. First tile from new molds are examined by the floor inspector, who also makes a daily report of the condition of ware on the drying floor. Before being scheduled for setting, the chief inspector satisfies himself as to the dryness. At the kiln, ware damaged from floor to kiln is rejected by the kiln inspector, who also prepares the drawing report showing quality and loss. All special ware is again inspected by the chief yard inspector for dimensions and quality before being loaded.

While it has not been possible to go into any detail, it is hoped that this discussion will serve to indicate a few of the many factors which have to be considered in directing the manufacture of refractory materials.

In conclusion, the writer wishes to acknowledge the courtesies extended by the management, and to express his indebtedness to A. B. Christopher, ceramic engineer, and J. W. Alexander, of the planning department, for information which was used in the preparation of this article.

Aczol—An Interesting Wood Preservative

MINING engineers and railroad men in this country have expressed a good deal of interest in a new wood preservative—new at least in this country. It had been used in Belgium particularly and on the continent of Europe for a number of years, but has never before been manufactured here.

Its name Aczol is derived from its ingredients—ammonia, copper, zinc and phenol. All of these component parts have been used to a greater or less extent in wood-preserving work. Copper and zinc have been used for a long time and phenol is an essential principle of creosote, which is at the present time the most widely used wood preservative. The novelty of this compound lies in the fact that the inventor has succeeded in producing this mixture in soluble form. It is entirely soluble during impregnation and precipitates after this is completed while the wood is being permitted to dry in the air. The drying causes the evaporation of the ammonia, which in this case simply acts as a carrier of the other material. The phenolic salts of copper and zinc become firmly imbedded in the wood fiber—in fact the sap and ligneous material is soluble in the solution and this liquid is replaced by the precipitated salts.

The impregnation of wood with creosote is accomplished by placing the wood in a large air tight vat. The air is then pumped out to as high a vacuum as possible and the heated creosote is put in under pressure. With Aczol the process can be conducted without the use of vacuum at all. This is, of course, a distinct advantage. It is reported, however, as would be expected, that a better impregnation takes place when vacuum and pressure are used. One distinct point of vantage, however, is the fact that no heat need be used on the solution. This use of heat is thought by some engineers to weaken the wood structure in creosote impregnation. Whether this is the case or not, creosote-impregnated wood is not as strong either in tensile or compressive strength as raw wood and, on the other hand, wood which has been impregnated with Aczol is much stronger, due, in all probability, to the cementing action of the salt in and around the wood fiber.

As compared with creosote, it has a number of advantages. It leaves the wood clean, dry, odorless and fire resisting. This last point is a distinct advantage. Furthermore, the wood can be tooled and worked exactly as untreated wood.

The material is manufactured in rather concentrated form and is diluted—six parts of the product to ninety-four parts of water in the field.

Severe Tests on the Continent

The interesting thing about this product from the standpoint of the American manufacturers is that it has already been tried out. Records of the use of wood impregnated with this material have been kept in Belgium for the past decade. In many coal mines it has been found necessary to renew timber in the return air galleries every 3 or 4 months. This is becoming an increasing expense with the diminution of our forests. When wood was relatively cheap, it did not worry mining engineers much and they said, "Oh well, we would rather put in a new piece than bother with impregnation." Especially was this true when creosote was known to be the best material, for very few persons cared to handle creosote. In Belgium coal mine operators testify that "aczolated" timber has remained in its original sound condition for 8 years. The difference is extremely notable.

Successful as Wood Paving

It has also been used successfully on wood paving. In Brussels during the war, the main street was paved with wood blocks which had been "aczolated." During 1914 the entire German war machinery—millions of soldiers with hobnailed shoes and numberless cannons and supply wagons—passed over these wooden blocks. They are, even now, in perfect condition 10 years after they were placed in use.

In America this product is made by Zinsser & Co., Hastings-on-Hudson, N. Y. No tests, of course, have been made in this country which would compare with the Belgian test, because the material is so new. The company has sample blocks of wood impregnated with this material which have been in mines for 6 or 7 years. Another use of aczolated wood is in railroad ties, where the rotting is extremely rapid, especially in some climates. The development of the use of this product will be watched with a very great deal of interest and it is predicted by a number of competent men that its use will rapidly displace that of creosote or similar work, not only because of its greater durability, but because of its greater ease of handling.

Synopsis of Recent Chemical & Metallurgical Literature

Durability of Sole Leather

Technologic Paper 215 of the Bureau of Standards describes the preparation of four lots of leather used to determine the comparative durability of sole leather filled with sulphite cellulose extract, and sole leather filled with ordinary vegetable tanning materials, such as chestnut wood and quebracho extracts.

Several hides were used in the preparation of each lot, and alternate sides were filled with the sulphite cellulose extract. Each pair of soles contained one sole prepared by each method, both of which were cut from the same hide and from similar locations.

The results of actual service tests are presented, which show that the average wear of the leather filled with sulphite cellulose extract was 9.08 days per unit thickness and of the ordinary leather 9.06 days.

Complete chemical analyses of both the new and worn soles are also given. The general conclusions are that there is no difference in the two leathers as reflected by the chemical analyses, that sole leather filled with sulphite cellulose extract is as durable as leather filled with chestnut wood and quebracho extracts and that the former could well be used in place of the latter materials, thereby conserving them for the actual tanning of leather, for which they are more suitable than sulphite cellulose extract.

Decarburization of Steel by Hydrogen

Charles R. Austin, of University College, Swansea, presented a long memoir on "Hydrogen Decarburization of Carbon Steels With Considerations on Related Phenomena" before the May, 1922, meeting of the British Iron and Steel Institute. He worked with several very pure steels, and examined the metal after 12 hours' exposure to a stream of moist hydrogen at various temperatures. The end result is due to two main factors (*a*) removal of carbon as methane and (*b*) diffusion of carbon from the unaffected core. At low temperatures (*a*) seems to be more important, therefore the line of demarcation between ferrite case and substantially unaltered core is very clearly marked. At high temperatures—roughly above the upper critical—(*b*) is of greater importance, therefore the carbon content decreases gradually.

At temperatures just below A_1 the depth of decarburization was a linear function of the time of exposure. Its actual amount becomes unobservable at about 500 deg. C., but reaches a maximum at about 1,000 deg. C. Measurements and calculations indicate that the amount of carbon diffusing across 1 sq.cm. in one day under unit concentration gradient (i. e., the diffusion constant) is equal to 0.005 at 650 deg. C., and 0.05 at 850 deg. C.

Columnar ferrite crystals were noted in the muffs of steels heated within the transformation range; equiaxed ferrite resulted from higher or lower decarburizations. Tendency for columnarization appeared in hypereutectoid steels at temperatures somewhat above and below this range. No columnar crystals could be developed in Armco iron. Consequently the author concluded that the elongated crystals were caused by the disturbing influence of hydrogen gas diffusing into and out of the steel. There are reasons for believing that this occurs more readily along the grain boundaries.

Growth of Cast Iron

It has long been known that gray cast iron increases in volume after repeated heatings, and the many investigators who have studied the phenomenon have divided into two camps—one which believes it due to internal oxidation, and another which thinks the main influence is the expansion of occluded gases.

Tario Kikuta, in the fifty-ninth report of the Iron and Steel Research Institute (*Science Reports*, Tohoku Imperial University, Sendai, Japan, vol. 11, p. 1) has measured the leakage of gas through the walls of a gray cast-iron tube at various temperatures, and finds that at room temperatures the leakage increases for sixty repeated heatings to 960 deg. C. Furthermore the leakage at elevated temperature is only slightly less than when cold. Therefore the view is untenable that air penetrates the iron at low temperatures, but cannot escape at high temperatures, and hence causes expansion of the iron. Density of a gray cast iron was also observed during repeated heatings under various circumstances. The greatest expansion was noted after repeated heatings *in vacuo*, followed by quenchings. Next was after heatings in air, followed by furnace coolings; air heatings followed by quenchings caused slightly less. The least expansion resulted from heatings and furnace coolings *in vacuo*.

Most instructive data were had by recording temperature-elongation curves. When working *in vacuo*, a large and sudden expansion occurred in gray cast iron during the first heating at 700 to 800 deg. C., caused chiefly by decomposition of cementite (a phenomenon which causes an extension of 2.5 per cent in white cast iron passing through this range). A slight contraction occurs when passing Ac_1, representing the solution of a certain amount of free carbon. This contraction approaches zero at about the fifteenth heating. On cooling, a larger and irreversible expansion occurs at Ar_1, an expansion which recurs with but slightly decreasing intensity on each cooling.

Oxidation can have little to do with this phenomenon, since the work was done in a vacuum. The author thinks that carbon, which goes into solution readily at the eutectoid areas, passes very slowly from the graphite flakes to the surrounding ferrite. On cooling, the eutectoid decomposes readily, expanding and splitting the surrounding ferrite low in carbon. Growth of these fractures occurs by repeated stresses during cooling, and consequently growth continues. Slow cooling should permit these stresses to relieve themselves somewhat; therefore furnace coolings *in vacuo* show the least expansion. Slowing down the rate of reaction is due to coagulation of graphite particles, as observed under the microscope. White cast iron, not having the duplex structure, does not grow on repeated heatings, the changes at the transformation being reversible. About one-third the total expansion is due to decomposition of cementite, the remainder to minute fissures caused by differential expansion of various microportions.

Gray iron heated in air exhibits the same phenomena as *in vacuo*. The expansions at Ar_1 are more intense at first, but slow down more rapidly. The contraction at Ac_1 is almost absent, thought to be due to the oxidation of iron along the graphite flakes, thus preventing solution at these areas. Large expansions during Ar_1 are also due to filling the cavities with oxide, preventing them from adjusting their volume to the surrounding conditions. Very slow heatings and coolings in air cause greater volume changes at A_1, thus being opposite to the effect in vacuum, a discrepancy explained by the author as due to the more extensive diffusion of carbon and the continuous oxidation of the ferrite ground mass.

Studies on Aluminum Alloys Capable of Improvement by Aging

W. Fraenkel and E. Scheuer (*Z. Metallkunde*, vol. 14, pp. 49 and 111, 1922) have investigated with great care the electrical conductivity of alloys of the Duralumin type, including those containing zinc, in the annealed, as quenched, naturally aged and artificially aged condition. Elasticity, resistance to corrosion, electromotive force in aluminum sulphate solution, thermo-electric force and density were also studied, the purpose being to learn the true explanation of the improvement which takes place during aging.

The change in specific resistivity during the aging is most significant, especially since marked differences were found in the behavior of the naturally aged (at room temperature) and artificially aged (at 100 deg. C.) specimens.

Starting with the annealed metal, they found that heat-treating and quenching increased the resistivity, which indicates that this operation has caused the formation of a solid solution. If the aging consisted in the precipitation of the dissolved components, as believed by Merica and others, it should be accompanied by a decrease

n resistivity. Actually, aging at room emperature was accompanied by an ncrease in resistivity, indicating that here must be some other phenomenon nvolved. Aging at 100 deg. C. caused he resistivity to decrease about as nuch as it increased when the aging ook place at room temperature. Nevrtheless the physical properties obained by these two methods of aging re practically identical.

The authors conclude that the aging nenomenon at low temperatures consists in the formation or increase in oncentration of a solid solution, as a esult of a chemical reaction between he additions (particularly magnesium) nd aluminum. Accordingly the aging onsists of two simultaneous changes —the chemical reaction and the formaion of the solid solution.

It is conceivable that one of these henomena might take place without he other. This case seems to occur vhen the aging takes place at elevated emperatures, since we have here the ncreased strength, but a decreased reistance. The increased strength is upposed to be due to the formation of he chemical compound.

Instead of considering the aged state f the alloy as a metastable one lying etween the "as quenched" state and he stable annealed state, as previous vorkers have done, the authors conider it more probable that it is the tate which is really stable at ordinary emperatures. After annealing and low cooling, the constituents are so nuch separated that the stable comound cannot form at a measurable ate, on account of the extremely slow ate of diffusion. The reaction can ake place only when the separation is revented by the rapid cooling of the olid solution obtained at the heatreatment temperature.

This theory, based on the measureents of electrical conductivity, is ound to be in harmony with the exeriments on the other properties, so ar as they can be interpreted.

Book Reviews

PRACTICAL TANNING. By *Allen Rogers, Ph.D.* 699 pages, 124 illustrations. New York: Henry Carey Baird & Co., Inc., 1922. Price $10.

While based in part on the third dition of Flemming's "Practical Tanning," the present volume bears little esemblance to the earlier ones, which vere simply collections of miscellaneous ecipes and formulas. Dr. Rogers has rouped related topics under suitable eadings and presented these in logical equence so that the whole forms a onnected story of the leather industry. Material from the earlier edition has een supplemented by data from Dr. Rogers' experience and from many ther sources. While it is obviously mpossible to present a manufacturing manual for such an extensive and aried industry within the space of a ingle volume, the tanner will find a reat number of suggestions relating to practical details of tannery operations.

The policy followed intentionally throughout the book of emphasizing the practical side to the almost complete exclusion of theoretical considerations would seem to imply that success in the tannery depends more upon having a good formula than upon an understanding of the nature of the reactions involved. This is not in accordance with the experience of many other industries and advance in the leather industry will be slow as long as empirical methods predominate.

While, as indicated above, the book has been prepared primarily for the practical tanner, it will be of interest to students and others desiring information regarding modern practice in leather manufacture. A variety of modern illustrations serve to increase the attractiveness of the volume.

ALAN G. WIKOFF.

DUST EXPLOSIONS. By *David J. Price* and *Harold H. Brown.* Published by National Fire Protection Association, Boston, Mass. 320 pp., 87 illustrations. 1922. Price $3.

This discussion of the theory, nature of and causes of dust explosions is by two authors whose names are already well known in the literature of this subject. In this particular work they are assisted by two other able investigators whose co-operation is acknowledged on the title page—namely, Hylton R. Brown and Harry E. Roethe. The two principal authors and these men associated with them are all members of the technical staff of the Bureau of Chemistry, in which department they are directly responsible for the work on dust-explosion prevention.

As pointed out in the preface of this work, the general subject has not received anything like serious consideration until very recently. However, the tremendous importance of protection of industrial establishments against the hazard of dust explosions is now well recognized.

This work will be of immense value to the construction engineer as well as to those responsible for operating practice. It gives a clean-cut, simple discussion of why a suspension of dust in the air will explode and makes clear not only the possible consequences of such explosions but also the practical means at hand for prevention of the formation of dangerous air-dust mixtures. All the way through the work the reader will be impressed with the very practical nature of the proposals made. It is a great relief to find a safety engineer who writes on such a basis, for all too often the man who specializes in safety devices permits his enthusiasm to run away with his judgment.

The problem of dust prevention is by no means confined to the agricultural and cereal-milling industries, in which lines the disastrous consequences of dust explosions have been most conspicuous. Recent events well illustrate the hazard in fertilizer, metal-powder, rubber, soap, spice, sulphur and many other chemically controlled industries. It will pay every operating management to get a copy of this work and read it carefully. Such reading will be suggestive of many hazards of serious moment which occur throughout the industry. Moreover, the work will suggest readily available means for correcting these conditions at nominal cost. The price of the work will thus be about the cheapest form of explosion insurance which a management can possibly buy.

R. S. MCBRIDE.

METALLURGY OF ZINC AND CADMIUM. By *H. O. Hofman.* 341 pp., 261 illustrations. New York: McGraw-Hill Book Co., 1922. Price $4.

This is the fourth of a series of notable metallurgical treatises by Professor Hofman, of the Massachusetts Institute of Technology. The most pretentious was the "General Metallurgy," issued nearly 10 years ago. The interval is none too much for such comprehensive volumes as Hofman's "Metallurgy of Copper," "Metallurgy of Lead" and the subject of the present review. To round out the series, a "Metallurgy of Minor Metals" and a "Metallurgy of Gold and Silver" are now in preparation.

A reader or student who is acquainted with any of the other volumes will recognize the form and style immediately. I presume that a certain rule was laid down for these treatises: they must be comprehensive and yet be compressed in size. A mere statement of fact is all that is permitted. But it's all there, together with footnotes telling the exact source of information, to which the student can go for further discussion and detail. Unfortunately this gives the impression that the author is merely a compiler—often it appears that a series of index cards were set into type. Such a rule unfortunately submerges the personality of the author, and even masks the fact that he must be acquainted with operating details in order to appraise, as he has done, the relative importance of various publications, and fill the gaps left by periodical literature.

"Metallurgy," as comprised by this volume, is the art of extracting marketable metal from the ore. A number of auxiliary subjects are outlined, such as the ores and chemistry of various chemical compounds. Certain auxiliary operations are also discussed which are not metallurgy, but which have always been done at the zinc smelter (not smeltery), notably the manufacture of retorts—which is pottery—and the manufacture of zinc oxide—which is pigment. A chemical engineer might claim that the important chapter on electrolysis is something else than metallurgy. But even though the book contains preliminary chapters on properties of zinc and its alloys, these matters are discussed merely in order to show what is required of good marketable spelter and the effect of various metallic impurities. The physical metal-

lurgy, metallography, heat-treatment and mechanical working of pure zinc and its remarkably important alloys are not mentioned.

This doubtless is in keeping with the division of the industry in America, where zinc is smelted wherever there is a confluence of ore, fuel and labor, and the metal sent down East to rolling mills and brass works established long before the first pound of virgin metal was won in the States. In fact the book is almost entirely confined to American practice. Thus it supplies a gap in literature; Mr. Ingalls' "Metallurgy of Zinc and Cadmium" is 20 years old, and the quite recent "Zinc Industry," by E. A. Smith, is confined almost exclusively with British conditions.

E. E. THUM.

PUBLICITY METHODS FOR ENGINEERS. 187 pages, illustrated. Chicago: American Association of Engineers, 1922. Price $1.50.

In discussions regarding the lack of real public appreciation of the importance of chemistry and the closely related topic of the diligence with which the average chemist avoids participating in public activities, reference is frequently made to the accomplishments of other professions. While the lawyer is almost invariably set up as the shining example, the engineer has quite often been included in the favored group. Consequently it was with a great deal of interest that the reviewer noted the following paragraph in the book under consideration:

"Take one illustration, as a typical example. 'Creative Chemistry,' a book by Edwin E. Slosson, can teach many lessons about making interesting reading of engineering productions. It originated in a series of articles prepared for the *Independent* in 1917-18, 'for the purpose of interesting the general reader in the recent achievements of industrial chemistry.' The original article and the book itself have been read by thousands of people who were interested in the author's presentation of otherwise dry chemical facts, and without question there has been a tremendous amount of valuable publicity for the chemical profession as a result. The same can be done with engineering subjects."

Chemists who are interested in getting chemistry across to the public—and every chemist should be—will find this book full of valuable suggestions. It is based on papers and discussions presented at the First National Engineering Congress on Public Information, which was held under the auspices of the American Association of Engineers in Chicago, Feb. 25, 1921. The excellent educational material presented at this conference has been edited to eliminate duplication and make easy reading in a handbook. Some idea of the method of treatment can be gained from the chapter headings: Some Reasons for Publicity; The Right Conception of Publicity; Ways and Means That Bring Publicity; Getting News Into the Newspapers; The Publicity Man and What He Needs to Know; Typical Publicity Problems. Approximate estimating cost and an outline of a working plan for public information are included as appendices.

From the chemists' point of view it is also of interest to note that the book closes with an extract from the talk on research information service by Dr. Charles L. Reese which was presented at the Birmingham meeting of the American Chemical Society.

ALAN G. WIKOFF.

CATALYTIC ACTION. By *K. George Falk.* The Chemical Catalog Co., 1922. 72 pages. Price $2.50.

CATALYSIS, WITH SPECIAL REFERENCE TO NEWER THEORIES OF CHEMICAL ACTION. A general discussion held by the Faraday Society. Reprinted from the *Transactions* of the Faraday Society, vol. 17, 1922. 172 pages. Price $2.50.

Dr. Falk has taken the themes which would form the introductory and theoretical chapters of a larger textbook of Catalysis and has expanded them into a 170-page volume. He has profited by the intensified interest displayed in these last years in the mechanism of catalytic processes and has produced a brief volume which should be stimulating and provocative to all chemists, not alone those interested in catalytic processes. For, stripped of the romance which even the chemist sometimes clothes his science—and, in catalysis, hitherto, romanticism has been uppermost—catalysis in its essentials is seen to be a branch of ordinary everyday chemistry and chemical reactions.

Having essayed an earlier, if less successful, volume on chemical reactions, Dr. Falk inquires in the present work how far the theory of intermediate compounds is applicable alike to catalytic phenomena. His answer is given in Chapter III, which demonstrates the applicability of the theory to a number of examples. Many of the catalytic reactions of organic chemistry are the more understandable by reason of such a theory, more especially those occurring in homogeneous systems. The postulation of intermediate compounds in catalysis or the elucidation of the pathway of a simple chemical reaction is, however, no longer soul-satisfying. Energetics, sub-atomic phenomena and the activity of radiation are now all being probed, as Chapter IV and V show, for their contributions to the general theory of reactions.

Chapter VIII, on Contact Catalysis, should have preceded Chapters VI and VII, on Enzyme Actions and the Chemical Interpretations of Life Processes. The point of view now developing with respect to reactions at interfaces involving oriented adsorption (Hardy, Langmuir and others) or the association of catalysts with reactants to form temporary unstable complexes, specific in nature (Armstrong and Hilditch), will go far toward elucidating the more complex life processes. Only the fringes of the problem here have, as yet, been reached. An enormous amount of experimental work is needed, upon the basis of theories now outlined. In that work the problem of promoter action, for which Dr. Falk finds no theory as yet, will find its solution. Let us hope that the perusal of the volume will send yet more experimentalists into the field, that the outline here presented may be enlarged and developed.

The reprint of the general discussion on "Catalysis, With Special Reference to Newer Theories of Chemical Action," conducted by the Faraday Society in September, 1921, has an interest for a far wider chemical audience than that particularly engaged in catalytic work. It emphasizes anew the important influence which a numerically small society can exercise in the development of chemical science. It is a challenge to those who are at present busied with the problem of improving the service which the American Chemical Society renders to its members through its stated meetings. For here we have a record of a symposium admirably organized, with papers preprinted for the members desiring to attend so that useful discussion may be possible. The contributors to the symposium were acknowledged experts and from many lands, Perrin of France, Langmuir, Arrhenius, Lewis, Baly and others. The argument was concentrated on well-defined aspects of the particular problem, the radiation theory in the one hand and surface reactions on the other. The mind of the meeting was thereby directed to definite issues and vagueness and diffuse generalities were accordingly absent. The whole was carefully matured long months before the meeting took place, little being left to the hasty activities of last minute enterprise. The genius of the organizing secretary, F. S. Spiers, should be noted and his procedure emulated.

The volume extends the benefit of the discussion to a wider audience. Herein may be found complements to the outline discussion in Dr. Falk's book. The section on the radiation theory represents the most comprehensive statement of the theory yet put forward. Perrin's brilliant exposé of theoretical aspects of the problem is supplemented by Lewis' statements of attempted experimental verification. Baly summarizes the point of view which has led him to his recent work on photocatalytic processes such as the hydrogen-chlorine combination, the mechanism of carbohydrate and protein synthesis. The discussion contributed by Langmuir and Lindemann enables the reader to maintain a just perspective as to the merits and defects of the theory.

In the section devoted to Surface Reactions it was fitting that both contributions should be by Langmuir. Here will be found a general résumé of the subject and a detailed study of platinum catalysis of the oxidation of hydrogen and carbon monoxide. The point of view and the experimental method are both useful as models for much future work.

HUGH S. TAYLOR.

Recent Chemical & Metallurgical Patents

American Patents

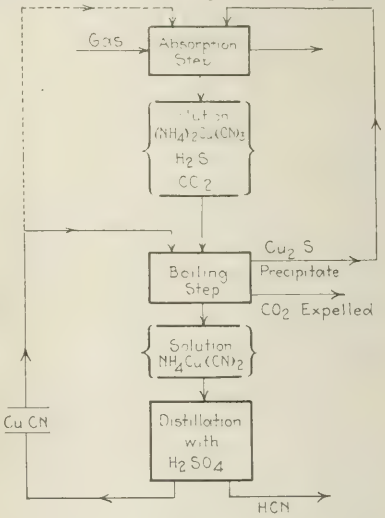
Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Oxidizing Olefines—A number of unusual products may be obtained by the oxidation of the hydrocarbons obtained in the cracking of petroleum distillates. Not long ago Professor James of the Carnegie Institute of Technology outlined a catalytic process for this oxidation which yielded, among other materials, a number of fatty acid products of very interesting properties. More recently Carleton Ellis, of Montclair, N. J., has been granted a patent for the oxidation of such or similar products by the use of nitric acid. As a raw material he uses the acid extract which may be obtained by dissolving the various olefine products in sulphuric acid, cooling and agitating to yield a solution of alkyl-hydrogen-sulphates or similar products. By treating this extract with nitric acid or with an oxygen-containing compound of nitrogen, various ketones and fatty acids are obtained. The process is not limited to the acid extracts, but is also applicable to the alcohols produced by the hydrolysis of such an acid extract. (1,418,368; assigned to Seth B. Hunt. June 6, 1922.)

Purifying Hydrogen — Hugh Scott Taylor and E. K. Rideal have developed a process for obtaining pure hydrogen by means of the well-known iron steam process. As used at present, the process produces hydrogen containing appreciable quantities of carbon monoxide and carbon dioxide, the latter of which impurities is easily removed. It is almost impossible, however, to remove the carbon monoxide by a simple process, and the authors showed in their researches that the proportion of steam increases in relation to the hydrogen present as the gases emerge from the iron retort during any single make period. (The make period is, of course, the period during which steam is allowed to flow through the hot iron.) During this same period the ratio of carbon monoxide to carbon dioxide decreases. Utilizing these two phenomena, the authors have developed what might be called a preferential combustion of the carbon monoxide to carbon dioxide by steaming the impure hydrogen. This changes the CO to CO_2. This process will have distinct advantage in industries where pure hydrogen is highly desirable, such as the hydrogenation of fats and oils. (1,411,760; April 4, 1922.)

Vulcanizing Caoutchouc—Clayton W. Bedford has patented the use of methylenediphenyldiamine as an accelerator in vulcanization. Combining this or another one of Schiff's bases with sulphur in the ratio of 198 to 64 gives a compound which he designates as the sulphur-nitrogen accelerator. This process is patented as well as the application to rubber. The producer also can be produced by using a solvent such as aniline with sulphur and methylene aniline. Still another form is being made by the use of methylene aniline (dipolymer) and sulphur alone. Vulcanization of a mix of 16 parts zinc oxide, 16 parts of rubber, 1 part of sulphur and 1 part of the accelerator takes about half the time required for vulcanization without the accelerator. In addition, a higher tensile strength, a higher modulus of elasticity and other properties are also claimed by the author. (1,418,772; June 6, 1922.)

Extraction of Cyanide From Gases—The object of these inventions is extraction of cyanides or hydrocyanic acid from gases in the form of alkaline cupro-cyanide and recovery as such or conversion to other cyanide compounds.



The scheme of operation for recovery of hydrocyanic acid is shown diagrammatically. The application of these reactions to the recovery of cyanides is obvious. (1,413,762 and -63; Max E. Mueller, of Youngstown, Ohio. April 25, 1922.)

Purification of Gases by Selective Oxidation—This process comprises the catalytic removal of catalyzer poisons from gases which are subsequently subjected to the action of catalysts. In this way the danger of poisoning or destroying the efficiency of catalysts is removed or substantially avoided.

The invention comprises the passing of the gases through a sorbent oxidizing catalyst at a low temperature, the gases being previously mixed with the necessary quantity of air or oxygen when the amount of impurities is large and when the amount is small, being without such admixture.

Among the objects of the invention is the removal of oxidizable gases such as carbon monoxide, from other oxidizable gases, such as hydrogen, in such gases as water gas or other gas mixtures and the removal of such impurities as arsine and phosphine from gases, such as acetylene, ammonia, or the like, to produce respectively pure hydrogen, acetylene, ammonia, etc., and to accomplish such removal at low temperatures. In other words, it might be said that one of the objects of the invention is to provide a process whereby combustible mixtures may be purified by selective oxidation of certain of the constituents.

It may be stated as a general rule that a mixture of metallic oxides consisting of two or more oxides, one being polyvalent and the other mono- or di-valent, will produce the desired oxidation, when properly prepared. The catalysts are active from the start even when operating at low temperatures. In other words, when the gases are brought in contact with the catalysts the oxidation begins at once.

The choice of the material to be used in any particular oxidation depends on the ease with which the oxidation takes place at the desired temperature, and the temperature at which the oxidation will take place will depend upon the quantity of the impurities in the gas and, to some extent, the humidity of the mixture.

The catalysts are prepared in the manner set out in the Patent 1,345,323, dated June 29, 1920, by J. C. W. Frazer and C. C. Scalione. These methods of preparation involve the initial preparation of the material in a very finely divided state, preferably by precipitation, substantially complete removal of the impurities, such as the excess of precipitant, collection of the material, thorough kneading in order to very intimately mix the constituents, formation into a more or less dense cake, and drying of the cake at low temperatures.

Specific examples of the preparation of a copper oxide catalyst and one composed of copper oxide or carbonate and manganese dioxide are given.

Other mixtures such as ferric oxide, manganese dioxide, bismuthic oxide and copper oxide may be used if properly prepared as indicated. (1,418,246; Joseph C. W. Frazer, Baltimore, Md., Arthur B. Lamb, Washington, D. C., and David R. Merrill, Newark, N. J. May 30, 1922.)

Coke-Oven Construction — The triangular flue oven which has been adopted in recent construction for the Koppers Co. installations is described by this patent. Claims for the improvement are increased flexibility in operation and adaptability of the oven for operation with either producer gas or coke-oven gas as the fuel. The invention also contemplates burning these fuel gases either with preheated air alone or with preheated air in an atmosphere containing large quantities of a neutral gaseous diluent which enables control of the combustion, even distribution of the heat over the entire heating wall area, and avoidance of the harmful effects of flame concentration. The structural advantages due to triangular instead of rectangular flues are also emphasized both from the standpoint of construction and operation of the oven. Features of con-

struction of the fuel gas, air and diluent-gas inlet and outlet valves are also covered in the description in some detail. (1,416,322; Joseph Becker, of Pittsburgh, Pa., assignor to the Koppers Co. of Pittsburgh, Pa.)

British Patents

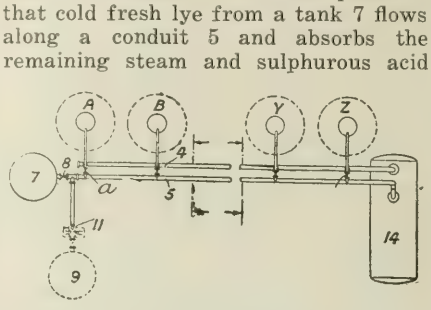
For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Vegetable Oil Extraction—The extraction of vegetable oils and fats by means of relatively low pressure is effected by humidifying the oleaginous matter before pressing so as to produce cellular exudation of the oil. The desired humidity may be obtained by exposing the material to steam or to atomized water until its weight has increased by 10 to 40 per cent. The pressing may be effected while the material is hot or cold, and one-tenth of the pressure employed in the usual process is sufficient. In the case of coconut oil and peanut oil pressures of 5 to 10 kg. per sq.cm. are suitable. (Br. Pat. 179,191; not yet accepted. Cellulose et Papiers Soc. de Richerches et d'Applications, Paris. June 28, 1922.)

Fertilizer From Waste Sulphite—A fertilizer is obtained by causing a reaction of waste sulphite lye from the manufacture of cellulose with matter adapted to bind the water of the lye. Quicklime or a mixture of quicklime and magnesia are suitable for the purpose. Hot concentrated lye is preferably used and peat dust may be added to the mixture. The product is ground for use, and fertilizing agents may be added either before or during grinding. (Br. Pat. 179,151; not yet accepted. Zellstoff-Fabrik Waldhof, Mannheim. June 28, 1922.)

Chromium Electrolysis—Alkali chromates are obtained by electrolysis of alkali carbonate solution with anodes of ferrochromium, and without a diaphragm. The chromate may be converted into bichromate by continued electrolysis after complete conversion of the carbonate. Concentrated solutions are preferably employed, so that the resulting chromate or bichromate solution is near the crystallizing point. To obtain neutral chromate, bichromate may first be formed and excess of alkali carbonate then added. Iron oxide is formed as a precipitate and is removed from time to time by agitation and filtration of the liquid or by centrifugal separation. The anodes may alternately consist of carbon chromite and tar heated below fusion to partially reduce the oxide of chromium. The cathodes may be of lead. Ferrochromium anodes should contain not less than 40 to 45 per cent of chromium. A high current density of some hundreds of amperes per square meter is employed so as to heat the electrolyte. Alternating current may be used. The electrolysis may be carried out in a series of baths between which the electrolyte circulates. (Br. Pat. 177,174; not yet accepted. A. J. B. Jouve and A. Helbronner, Paris. May 10, 1922.)

Sulphite Cellulose—In regenerating the waste heat and sulphurous acid from a system of sulphite cellulose boilers *A, B—Y, Z*, valves leading by conduit 4 to the tank 14 are opened and the pressure thus reduced to about 2 atmospheres. These valves are then closed and valves *a* and 8 are opened so that cold fresh lye from a tank 7 flows along a conduit 5 and absorbs the remaining steam and sulphurous acid



evolved by the boilers *A, B—Y, Z* and is collected in the tank 14, where it is finally saturated to the desired degree with sulphurous acid. The lye may run by gravity from the tank 7, or may be forced from a lower tank 9 by a pump 11. (Br. Pat. 179,150; not yet accepted. Zellstoff-Fabrik Waldhof, Mannheim. June 28, 1922.)

Magnesium Carbonate — Magnesium carbonate is prepared from dolomite by treating a suspension of the burnt dolomite in water or alkaline carbonate solution with carbon dioxide under ordinary, diminished or increased pressure, the proportion of burnt dolomite being so adjusted that "in the treatment the magnesia in the dolomite is always present as a deposit." In an example, 100 kg. of burnt dolomite are mixed with 1,500 liters of water, and treated with carbon dioxide under pressure. The mixture is filtered, and about 70 kg. of hydrated magnesium carbonate is obtained from the filtrate by heating. (Br. Pat. 176,785. T. Simon, Mark, Germany. May 3, 1922.)

Decomposing Leucite—Aluminum and potassium chlorides are separated from solutions of leucite in hydrochloric acid by the following cyclic process. A hot, highly saturated solution of leucite in hydrochloric acid is cooled to atmospheric temperature, when most of the potassium chloride crystallizes and is removed. The molten liquor is then treated with gaseous hydrochloric acid either by spraying the liquor into the gaseous hydrochloric acid or by passing the latter into the mother liquor. The aluminum chloride, which is thereby precipitated, is removed, and the mother liquor is used for treating fresh quantities of leucite. (Br. Pat. 176,770; not yet accepted. G. A. Blank, Rome. May 3, 1922.)

Treating Chromium Ores—Ores containing oxides of chromium are treated for the purification or concentration of the chromium constituent by submitting the ore to the action of a halogen or gaseous halogen acid, for example chlorine or hydrochloric acid, or a mixture thereof, with or without the addition of hydrogen, at such a temperature as to convert some of the constituents of the ore into volatile halogen derivatives. The temperature or the nature of the halogen atmosphere may be adjusted or varied so as to obtain selective distillation of the halogen derivatives; or two or more derivatives may be volatilized and collected together, or separately collected by fractional condensation or by absorption in a solvent for one or more of the constituents. For example, the iron may be volatilized from crushed and washed chromite by treatment at about 900 deg. C. with a mixture of hydrochloric acid and hydrogen, the chromium being afterward volatilized by raising the temperature to 1,200 deg. C. and passing chlorine over the residue; or the iron and chromium may be volatilized together by heating throughout at 1,200 deg. C. (Br. Pat. 176,729. W. H. Dyson, Ringwood, Normandy, and L. Aitchison, Birmingham. May 3, 1922.)

Loading Paper Pulp—The mineral salts, such as barium sulphate, used as filling for paper pulp, are maintained in suspension by the addition of water glass. Magnesium chloride solution or other salts, or acids, which precipitate the silica, may be used. Where mineral carbonates are used, their conversion into salts is preferred. (Br. Pat. 177,137; not yet accepted. F. Reichard, Berlin, May 10, 1922.)

Sulphur—Finely divided or colloidal sulphur is obtained by evaporation of ammonium polysulphide solution in presence of a protective colloid. Various protective colloids, or waste materials containing them, may be used, as for example saponines, gelatine, casein, sodium lysalbinate, waste sulphite liquor, naphthol pitch and glycerine foots. Evaporation of the solution may be accomplished in any convenient way; also, it may be continued until evolution of ammonia and hydrogen sulphide is complete, or the solution remaining after the removal of part of these gases may be neutralized with acid and then treated with an oxidizing agent, when the sulphur liberated from the hydrogen sulphide is also obtained in the colloidal state. In an example, a concentrated solution of ammonium polysulphide is run slowly into a boiling 0.5 per cent solution of soap. A white milk of sulphur is obtained. This may be removed from the solution, for example by the addition of an electrolyte, and the mass, after separating, may be reconverted into a stable sol by shaking with water. (Br. Pat. 117,103. Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. May 10, 1922.)

Litharge—Litharge is produced by the auto-oxidation of very finely divided lead. The lead is first powdered by putting lead balls into drums slowly revolving at, for example, 25 r.p.m. The oxidation is started by moisture or heat and then proceeds of itself; more lead power is added at a proper rate. The litharge can be converted into red lead according to known practice by heating in a furnace or pan at a temperature below 500 deg. C. (Br. Pat. 176,924. G. Shimadzu, Kyoto, Japan. May 10, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Montreal Program Promises Big Meeting for American Electrochemical Society

Many Attractions of Canadian City and Social Features Will Add to the Attraction of Strong Technical Program

FOLLOWING its customary agreeable practice of tempering a strong technical program with just the right amount of social and entertainment features, the American Electrochemical Society has completed plans for its Montreal meeting, Sept. 21 to 23. The Society headquarters will be at the Windsor Hotel, where registration will begin Wednesday evening, Sept. 20.

The Canadian city offers a number of attractions which aid in making it an ideal location for a convention of this kind. The drives about Montreal, in the Mountain Park, around Mount Royal and along the banks of the St. Lawrence and Ottawa rivers afford delightful views, unsurpassed in America. On Sherbrooke Street is one of the most beautiful buildings on the continent—the art gallery of the Art Association of Montreal. It has a splendid collection of paintings and sculptures. Within a stone's throw is also McGill University, with its magnificent buildings and campus. The Redpath Museum, one of the university buildings, is well worth a visit.

At Ste. Anne de Bellevue, 25 miles from Montreal and reached either by boat or train, is the Macdonald Agricultural College, built and equipped at a cost of over $5,000,000 and presented to McGill University.

The most interesting of all the old French buildings is the Chateau de Ramezay, named after Claude de Ramezay, the eleventh Governor of Montreal, who was born in France in 1657. The Chateau de Ramezay was built in 1705 as a mansion for the famous Baron de Longueuil.

There is one experience which no visitor should miss, and that is to "shoot" the famous Lachine rapids. These rapids are formed by the leaping of the St. Lawrence River over rocky ledges as the river descends swiftly to the level of the Montreal harbor.

Social Features

The Kanawaki and the Royal Montreal (Dixie) Golf clubs will afford golf enthusiasts an opportunity to compete for the Society championship. On Friday evening an old-fashioned smoker will be given by the local committee at the Windsor Hotel.

The visiting ladies will be entertained by sightseeing trips, theater parties and teas at the golf clubs. On Thursday evening the ladies will attend a lecture by Prof. A. S. Eve on "The New Philosophy of Physics" at McGill University.

Local members of the Society of Chemical Industry, Engineering Institute of Canada, Canadian Institute of Mining and Metallurgy, the faculty staff of McGill University and of Montreal University (Ecole Polytechnique) are cordially invited to attend the meetings and entertainments.

Excursions

There will be a special private train to Shawinigan Falls, leaving Windsor Station Friday at 11.30 at night, arriving at Shawinigan Falls at 7.30 a.m. The members will have a rare opportunity to inspect the following industrial plants: Belgian Industrial Co., Canada Carbide Co., Canadian Carborundum Co., Laurentide Power Co., Laurentide Pulp & Paper Co., and the Shawinigan Water & Power Co.

Opportunity will also be afforded for visitors to inspect the numerous industrial establishments in the vicinity of Montreal, including the St. Lawrence Sugar Refinery Co., Canada Cement Co., Imperial Oil Co., Dominion Engineering Works and the C. P. R. Angus shops.

The technical sessions on Thursday and Friday will be held in the Auditorium of the Windsor Hotel. The program follows in full:

Thursday, Sept. 21

10 a.m. Session for Reading and Discussion of Papers.

Norman B. Pilling: Effect of Heat-Treatment on the Hardness and Microstructure of Electrolytically Deposited Iron.

R. P. Neville and J. R. Cain: The Preparation and the Mechanical Properties of Vacuum-Fused Alloys of Electrolytic Iron With Carbon and Manganese.

Ralph B. Abrams: The De-zincification of Brass.

Walter G. Traub: Electroplated Zinc and the Diffusion of Electrodeposits Into Zinc.

John T. Ellsworth: The Effect of Single Impurities on the Deposition of Zinc From Sulphate Solutions.

M. R. Thompson and C. T. Thomas: The Effect of Impurities in Nickel Salts Used for Electrodeposition.

Ernest A. Vuilleumier: The Application of the Contractometer to the Study of Nickel Deposition.

12:45 p.m. Adjournment.

1 p.m. Meeting of board of directors at luncheon, Windsor Hotel.

2 p.m. Session devoted to papers and discussion on "Industrial Heating"; Bradley Stoughton, chairman, Electrothermic Division.

Charles P. Steinmetz: The Underlying Principles of the Industrial Heating Problem.

E. F. Collins: Electric Heat; Its Generation, Propagation and Application to Industrial Processes.

E. J. Smalley: Principles of High-Temperature Furnace Design.

Wirt S. Scott: Advantages of Industrial Electric Heating.

M. A. Hunter and A. Jones: Some Electrical Properties of Alloys at High Temperatures.

C. E. Williams: Resistivities of Some Granular Resistor Carbons.

J. C. Woodson: Heat-Insulating Materials for Electric Heating Apparatus.

Friday, Sept. 22.

9:30 a.m. Session on "Industrial Heating"; Part II.

Frank W. Brooke: Methods of Economically Handling Materials in Electric Furnaces.

Wirt S. Scott: The Development of Industrial Electric Heating for Low-Temperature Enameling.

E. T. Smalley: Treatment of Ceramics.

(Continued on page 519)

English Engineering Societies Form Joint Council

It is announced that proposals for closer co-operation among the leading English engineering institutions, which have recently been under consideration, have now received the approval of the institutions whose representatives met in conference—namely, the Institution of Civil Engineers, Institution of Mechanical Engineers, Institution of Naval Architects and Institution of Electrical Engineers—and that an Engineering Joint Council composed of representatives of these bodies has been formed.

The objects of the Joint Council will be, among others, to improve the status of engineers, to obtain the better utilization of their services in the country's interests and the appointment of properly qualified individuals to responsible engineering positions, and to prevent the unnecessary duplication of activities. At a later stage the number of bodies represented on the Joint Council may be increased.

Government Begins Chemical Foundation Suit

Equity Proceedings to Be Conducted in Delaware—List of Preferred Stockholders Numbers 158 Firms

ANNOUNCEMENT by Attorney-General Daugherty that the government's suit against the Chemical Foundation will be filed within the week was made Aug. 29. The original intention of bringing the suit in the District of Columbia has been abandoned and the equity proceedings will be started in Delaware, the state in which the Foundation was incorporated.

For the present, the American industry centers in the Chemical Foundation, which acts as trustee for American manufacturers whom it licenses. Its opponents charge that it obtained patents worth millions for $250,000. The Foundation asserts that this opposition comes from the former German owners of the patents who themselves wish to profit at the expense of the American industry, whose upbuilding is vital to national defense and whose development is resulting in cheaper prices for dyes and chemicals.

Finances of the Foundation

Capitalized at $500,000, the Chemical Foundation has 4,000 shares of preferred and 1,000 shares of common, par value $100 each. Both issues are restricted to 6 per cent dividends out of earnings which, in their option, the Foundation's trustees may distribute. Surplus must be used for educational work. To date no dividends have been paid. Preferred stock is retirable at the option of the trustees. It has no vote. It represents what thus amounts to a voluntary and practically complimentary advance to assure the early financing of the Foundation's activities, or cash-down ambition of American business to further develop a new industry in the experimental stages of which hundreds of millions have been invested.

Any qualified manufacturer may receive a license from the Chemical Foundation. Payment for the privilege is made in royalties ranging from 5 per cent down. Materials for the government may be manufactured without royalty. In the 3 years of its existence, the Foundation has shown a deficit of over $200,000, accounted for by expenditures of $260,000 in publicity and educational work. In the same period the United States Treasury has received $356,090 in royalties from thirty-five licensees of sixty licensed patents granted by the Federal Trade Commission. The Foundation has entered suit to recover this amount.

The Chemical Foundation holds 5,068 patents, 873 trademarks, 492 copyrights, 55 contracts and 22 applications, for which it paid $271,850.

List of Stockholders

The complete list of preferred stockholders of the Chemical Foundation follow, published now for the first time, follows:

Abbott Laboratories, Chicago, $800; Althouse Chemical Co., Reading, Pa., $400; Aluminum Co. of America, Pittsburgh, $800; American Aniline Products, Inc., New York, $800; American Cellulose & Chemical Manufacturing Co., Ltd., New York, $800; American Chemical Society, New York, $800; American Cotton Oil Co., New York, $800; American Platinum Works, Newark, N. J., $800; American Printing Co., New York, $800; Aniline Dye & Chemical Co., Inc., New York, $800; Arnold Print Works, North Adams, Mass., $800; Armour Fertilizer Works, Chicago, $800; Aspinook Co., Jewett City, Conn., $800; Atlantic Dyestuffs Co., Boston, $400; F. E. Atteaux, Boston, Mass., $800; Ault & Wilborg Co., Cincinnati, $3,100.

H. J. Baker & Bros., New York, $800; Baker & Co., Inc., Newark, N. J., $800; George A. Ball, Muncie, Ind., $800; Joseph Bancroft Sons Co., Wilmington, Del., $800; The Barrett Co., New York, $6,500; The Bayer & Co., Inc., New York, $800; Bethlehem Steel Co., Bethlehem, Pa., $800; C. Bischoff & Co., New York, $800; Borne, Scrymser & Co., New York, $800; H. Bowker Chemical Manufacturing Co., Philadelphia, $800; Bronx Co., New York, $800; Brown & Co., Portland, Me., $800; Butterworth Judson Corp., New York, $6,500.

John Campbell & Co., New York, $3,100; Capudini Chemical Company, Raleigh, N. C., $400; Chemical Dyestuffs & Chemical Co., Newark, N. J., $7,200; Antonin Chapel (Catskill Chemical Co.), Brooklyn, $800; Cheney Brothers, South Manchester, Conn., $800; Citro Chemical Co., Maywood, N. J., $400; B. P. Clapp Ammonia Co., New York, $400; R. H. Comey Co., Brooklyn, $800; Commercial Research Co., New York, $800; Commonwealth Chemical Corp., New York, $400; Consolidated Color & Chemical Co., New York, $6,500; Contact Process Co., Buffalo, $800; Crocker Burbank & Co., Fitchburg, Mass., $800; Samuel A. Crozer & Son, Upland, Pa., $800.

Davison Chemical Co., New York, $800; John C. Dehls, Newark, N. J., $800; Dermatological Research Laboratories, Philadelphia, $800; Detroit Chemical Works, Detroit, Mich., $400; Diamond Alkali Co., Pittsburgh, Pa., $800; Dicks-David Co., Inc., New York, $400; Digestive Fermints Co., Detroit, Mich., $400; John V. N. Dorr, New York, $800; Dow Chemical Co., Midland, Mich., $1,500; E. I. du Pont de Nemours & Co., Wilmington, Del., $84,100; Durex Chemical Co., New York, $400; Winthrop C. Durfee, Boston, $800; Dye Products & Chemical Co., Inc., New York, $400.

Eastern Drug Co., Boston, $800; Electric Boat Co., New York, $800; Electro Bleaching Gas Co., New York, $800; Charles Engelhard, New York, $800; The Essenkay Products Co., Chicago, Ill., $800; Essex Aniline Works, Inc., Boston, $500.

General Bakelite Co., New York, $800; General Ceramics Co., New York, $800; General Chemical Co., New York, $33,500; General Electric Co., Schenectady, N. Y., $800; Genesee Pure Food Co., Le Roy, N. Y., $800; George L. Gilmore, Lexington, Mass., $800; The Grasselli Chemical Co., Cleveland, $20,000.

Harovia Chemical & Manufacturing Co., Newark, N. J., $800; Hardwick & Magee Co., Philadelphia, $800; The Heller & Merz Co., Newark, N. J., $13,200; Hercules Powder Co., Wilmington, Del., $800; Herf & Frerichs Chemical Co., St. Louis, $800; Hess Goldsmith & Co., Inc., New York, $800; Heyden Chemical Works, Garfield, N. J., $800; Hooker Electro Chemical Co., New York, $6,500.

Irvington Smelting & Refining Works, New York, $800; Isco Chemical Co., New York, $800.

Johnson & Johnson, New Brunswick, N. J., $800.

Kelly-Springfield Tire Co., New York, $800; E. C. Klipstein & Sons Co., New York, $800; Walter E. Knipe & Sons, Philadelphia, $800.

La Belle Iron Works, Steubenville, Ohio, $800; Lackawanna Steel Co., Lackawanna, N. Y., $800; Lehn & Fink, Inc., New York, $800; Lewiston Bleachery & Dye Works, Boston, $800; Eli Lilly Co., Indianapolis, $800; Lindsay Light Co., Chicago, $800; Lonsdale Co., Providence, $800; Lowell Bleachery, Lowell, Mass., $800; John Lucas & Co., Inc., Philadelphia, $800.

Mallinckrodt Chemical Works, New York, $800; Marden, Orth & Hastings (Calco Chemical Co.), Bound Brook, N. J., $33,500; Francis T. Maxwell, Rockville, Conn., $800; McKesson & Robbins, New York, $400; Merck & Co., New York, $6,500; William S. Merrill Co., Cincinnati, $400; Merrimac Chemical Co., Boston, $11,900; Metals Disintegrating Co., Inc., New York, $400; H. A. Metz Laboratories, Inc., New York, $6,500; Millville Manufacturing Co., Philadelphia, $800; Monroe Drug Co., Quincy, Ill., $400; Monsanto Chemical Works, St. Louis, $800; George H. Morrill Co., Norwood, Mass., $400; Mt. Hope Finishing Co., North Dighton, Mass., $800; Mutual Chemical Co. of America, New York, $800.

National Ammonia Co., St. Louis, $800; National Aniline & Chemical Co., New York, $25,100; National Electrolytic Co., Niagara Falls, $800; National Silk Dyeing Co., Paterson, N. J., $800; The Naugatuck Chemical Co., Naugatuck, Conn., $800; New Bedford & Agawam Finishing Co., East Wareham, Mass., $400; The Newport Co., Milwaukee, $13,200; Niagara Alkali Co., Niagara Falls, $800; Niagara Electro Chemical Co., Niagara, $400.

Ohio Chemical & Manufacturing Co., Cleveland, $800.

Pacific Mills, Boston, $800; Parke, Davis & Co., Detroit, $800; Joseph E. Patchett, Keyser, W. Va., $800; Peerless Colors Co., Inc., Bound Brook, N. J., $800; Pennsylvania Salt Manufacturing Co., Philadelphia, $800; Permutit Co., New York, $800; Perth Amboy Chemical Works, Perth Amboy, N. J., $400; Charles Pfizer & Co., Inc., New York, $800; Philadelphia Textile Machine Co., Philadelphia, $800; Philadelphia Tapestry Mills, Philadelphia, $800; Powers, Weightman & Rosengarten Co., Philadelphia, $800.

The Rector Chemical Co., New York, $400; Republic Iron & Steel Co., Youngstown, Ohio, $800; Rhodia Chemical Co., New York, $800; The Roessler & Hasslacher Chemical Co., New York, $800.

Sayles Finishing Plants, Saylesville, R. I., $800; Schieffelin & Co., New York, $400; Solvay Process Co., Syracuse, $800; Semet Solvay Co., Syracuse, $6,500; Sherwin-Williams Co., Cleveland, $3,100; Frederick Stearns & Co., Detroit, $400; J. L. Stifel & Sons, Wheeling, W. Va., $800; E. R. Squibb & Sons, New York, $800.

Tartar Chemical Works (Royal Baking Powder Co.), New York, $400; Toch Brothers, New York, $400.

Union Carbide & Carbon Co., New York, $800; Union Bleaching & Finishing Co., Greenville, S. C., $800; United Drug Co., Boston, $800; United Piece Dye Works, Lodia, N. J., $800; United States Color & Chemical Co., Boston, $1,800; United States Finishing Co., New York, $800; United States Industrial Alcohol Co., New York, $800; The Upjohn Co., Kalamazoo, Mich., $800.

The Viscoloid Co., Leominster, Mass., $800.

George J. Wallau, New York, $800; The Wanskuck Co., Providence, $800; West Virginia Pulp & Paper Co., New York, $800; Western Electric Co., Inc., New York, $800; Jacques Wolfe Co., Passaic, N. J., $800.

Youngstown Sheet & Tube Co., Youngstown, Ohio, $800.

Zinsser & Co., Hastings, N. Y., $800.

Preferred Shares Have No Vote

Holders of preferred shares have no vote. The entire voting control is confined to the common stock, which is in trustees' hands.

These trustees are Otto T. Bannard, chairman of the New York Trust Co.; George L. Ingraham, former presiding justice of the Appellate Division of the Supreme Court of New York; Cleveland H. Dodge of New York; B. Howell Griswold, Jr., of Alexander Brown & Co., Baltimore, and Bradley W. Palmer of Boston. The trusteeship extends until 1936, by which time all patents will have expired.

Make Rapid Progress on Tariff

Conferees Postpone Controversial Points Until Last—Changes in Rates Not Announced but Expected in Chemical Schedule

DRIVING at top speed, Republican conferees on the tariff bill have considered and tentatively agreed upon more than half of the amendments to rates which were made by the Senate. Working 7 hours daily and with prospects of night sessions, the conferees have declared that their report will be submitted to Congress by the middle of September.

In making this record of speed, however, the conferees have passed over until the last all highly controversial points in the measure. The question of the basis of valuation to be used in determining ad valorem rates will not be taken up until the rest of the bill has been disposed of. The House used American valuation as its basis—the value of a comparable American article. The Senate used foreign valuation, which has been the basis of all previous tariff measures. In proceeding with discussion of rates, the conferees are using the Senate basis of foreign valuation, but with experts of the Tariff Commission keeping a parallel column translating such duties into terms of the American wholesale selling price of the imported article. This is the so-called Burgess plan, suggested by William Burgess, now a member of the Tarriff Commission, and which was considered and rejected by the Senate Finance Committee when the bill first came from the House more than a year ago. If this plan finally were adopted by the conferees, it would change every ad valorem rate in the bill—and ad valorem rates constitute about 22 per cent of all rates in the bill—and would destroy any accurate basis of comparison with previous tariff laws.

When the House of Representatives debated the rule under which the tariff bill was sent to conference on Aug. 22, an opportunity was given to the leaders on each side of the aisle to express their opinions as to the merits of the measure.

Political Situation

It was predicted freely on the Democratic side that it is the intention of the Republicans to keep the bill in conference until after the election. As long as the bill is in conference, it is contended, a candidate for office can go before the people and promise a favorable outcome in conference on questions where his constituents want to see higher rates and predict the modification in conference of rates which would be hard to defend.

Republican members did not deny that the bill would be held in conference until after the election and it was charged that Democratic campaign members have arranged for price advances on a large number of articles for which increased duties are being provided. If the bill is brought out just prior to the election it was charged that the Democrats have an understanding with importers to advance certain prices arbitrarily with the idea of influencing votes. This would be made possible, it was stated, by the relationship between importers and retailers.

On the other hand, it was contended that the Republicans were afraid to go before the country after having written ridiculously high rates in the law. Emphasis was placed upon assertions that Republicans are divided as never before on the matter of tariff rates. It was stated that many of the great manufacturing interests oppose high rates on the ground that they restrict their foreign market. In addition large loans have been made abroad and it was asserted that American financiers realize that repayment depends to some extent at least on sales made to the United States. One speaker urged the Republicans to bury their tariff bill. "There is already reaction against it," he said. "What we need is not new barriers, new obstacles, new difficulties, but the opening and broadening of the channels of communication between the peoples of the earth."

The Republican answer to that argument was that America's high place in the world as an economic power is the result of the application for over 100 years of the policy of taxing foreign producers for the privilege of selling their products in our markets.

Proceedings Secret

Nothing as to definite agreements on rates is being given out by the Republican conferees. The Democratic conferees are excluded from the sessions and no meetings are being held with reporters, as was done during conference on the tax bill.

Senator McCumber, however, has stated definitely that in the chemical schedule the conferees passed over coal-tar products, rates on which were increased heavily in the Senate by the Bursum amendment, raising the figures and placing them on the basis of American valuation. He also stated that white arsenic, on which the House placed a duty of 25 per cent and the Senate Finance Committee recommended 2 cents per pound but which was placed on the free list by vote of the Senate, had been passed over. It is expected that in the cotton schedule, the additional duty of 4 per cent imposed by the Senate upon yarns and cloths treated with vat dyes will be passed over until the dye rates in the chemical schedule are determined.

While no authoritative information has been given out by the conferees, it is the general understanding in the corridors of both houses of Congress that the conferees have made some reductions in the chemical schedule and in the metals schedule, the latter being in manufactured articles. The cutlery rates were passed over, it is understood.

Expect Fight on Dyes

When the conferees take up the coal-tar rates in the chemical schedule, a vigorous contest is expected. Senator Smoot is opposed to anything like the rates imposed by the Bursum amendment. Somewhat significant of the fight he proposes to wage in the conference was the fact that on the day the bill passed the Senate the Utah Senator obtained adoption of an amendment to the flexible tariff provision of the administrative section which would empower the President to make effective a change in rates of coal-tar products on 15 days' notice, whereas 60 days' notice is required before changes on any other products shall go into effect.

On the other hand, Senator McCumber heartily favors the high rates of the Bursum amendment, and Senator McLean, the third Senate conferee of the Republicans, voted for the high rates and is an ardent protectionist.

Of the House conferees, Representative Fordney, chairman of the Ways and Means Committee, while advocating high rates for dyes and chemicals, has indicated that he believes the Bursum rates "rather high." Mr. Fordney opposed the dye embargo, which was rejected by the House. Representative Longworth favored an embargo and it is believed that he will advocate very high rates of duty on dyes and chemicals. Representative Green of Iowa is rather an unknown quantity in this particular case and it is believed that his attitude largely will determine the issue.

Republican leaders in both House and Senate predict that the new tariff bill will be on the statute books by Oct. 1.

Alpha Chi Sigma Dinner

The dinner of Alpha Chi Sigma, the professional chemical fraternity, which is scheduled for Thursday evening, Sept. 14, at Keen's Chop House, New York City, will be mainly an informal get-together, and the main efforts will be directed toward giving everybody a pleasant evening. No formal talks have been arranged, and it is the arrangement committee's intention to allow the meeting to proceed spontaneously.

The one matter of importance that is to be considered at any length is the fraternity's plan for organizing the alumni members. At present, the strength and enthusiasm of the fraternity is centered in the undergraduate chapters, where there is little real necessity for it. The fraternity has already launched plans to extend the active organization to include graduates and active chemists all over the country, so that Alpha Chi Sigma will more truly rank as a professional fraternity.

Photographic Society Appoints Committees

Steps Taken to Assure Success of Exhibition and Meeting—Chamot Speaks

In connection with the activities of the Technical Photographic and Microscopical Society, which is planning an exhibit and meeting at the Chemical Exposition, a meeting of a number of the active members and officers was called for Aug. 30 at the Chemists' Club in New York. T. J. Keenan, secretary of the society, emphasized the fact that in view of vacancies on the executive committee, there was need of a temporary committee to carry out the details of the program. The following committee was appointed to conduct the affairs of the society in connection with the exposition and annual meeting, when the personnel of the executive committee will be completed: E. R. Morton, chairman, D. S. Mungillo, J. A. Lucas, D. G. Woolf, J. A. Scheick and J. Gibbs. This committee will work in co-operation with the society's exhibition committee, of which A. E. Buchanan is chairman.

A nominating committee was also appointed, consisting of M. W. Cohen, A. E. Buchanan and P. F. Wehmer. Names of the nominees will be presented to the annual meeting of the society at the Grand Central Palace on Sept. 14.

PROF. CHAMOT'S INTERESTING TALK

An interesting talk was delivered by Prof. E. M. Chamot of Cornell University at this meeting, in which the well-known microscopist pointed out some of the things that he hopes the society will accomplish. The speaker mentioned the need for specially designed instruments for industrial microscopical work. The needs of the biologist and bateriologist do not coincide with those of the industrial microscopist, he said, yet the design of standard equipment is entirely dominated by the demands of the former because it is a well-established demand. By the concerted efforts of industrial workers it may be possible to convince instrument makers that there is a field for special apparatus that is worth their attention and thus eliminate the necessity of giving this business to foreign instrument makers.

Dr. Chamot expressed the hope that the society will be able to combat the misguided secrecy that surrounds so many industrial establishments. The war, he said, did much to break down this traditional attitude of mysticism that some firms assume with the idea of keeping their professional secrets from competitors. The technical societies can do a great deal to show proponents of this obsolete idea what a short-sighted policy it really is and how much better work would be done by the employees if a company would encourage their mixing with their coworkers from other organizations and freely interchanging ideas.

Manufacturing Chemists' Association Will Aid DeLong

The executive committee of the Manufacturing Chemists' Association will serve as an advisory committee to the Chemical Commodity Division of the Department of Commerce. This committee will make a survey of the situation and will submit recommendations to Secretary of Commerce Hoover as to how the division can be most useful to the chemical industries. This arrangement was worked out at a conference in which the following participated: Secretary Hoover; Julius Klein, director Bureau of Foreign and Domestic Commerce; C. R. DeLong, chief of the Chemical Commodity Division; Henry Howard, chairman of the executive committee Manufacturing Chemists' Association; S. W. Wilder, Merrimac Chemical Co.; Robert T. Baldwin, National Aniline & Chemical Corporation; Gilbert Currie, Dow Chemical Co.; M. R. Kienle, Mathieson Alkali Co., and John Tierney, Washington representative of the Manufacturing Chemists' Association.

The executive committee of the Manufacturing Chemists' Association will meet Sept. 20 to formulate the recommendations that will be submitted to Secretary Hoover.

Prominent Speakers at Chemical Show

Government Representatives to Discuss Live Subjects During Exposition

Acting Secretary of War J. M. Wainwright has accepted an invitation to address the opening meeting of the National Exposition of Chemical Industries on Monday evening, Sept. 11, at 8 p.m. The title of his address will be "The Relation of the Chemical Industry to National Defense."

Another speaker that will attract many is Wayne B. Wheeler, counsel for the Anti-Saloon League, who speaks on Monday evening, Sept. 11, at 8 o'clock on "The Attitude of the Anti-Saloon League Toward Industrial Alcohol." One of the most vital subjects in the chemical industry today, a discussion of the alcohol question by so eminent an authority as Wheeler will undoubtedly bring out the local chemical, drug, flavoring extract, perfume and allied consuming industries en masse.

On the same evening C. P. Smith, Assistant Commissioner of U. S. Internal Revenue, will fully discuss the subject of industrial alcohol by reviewing the government's regulations upon this commodity.

The Chemical Division of the U. S. Department of Commerce will be represented, with the Bureau of Mines and the Bureau of Chemistry. C. R. DeLong of the Department of Commerce will speak on Sept. 12 at 8 p.m. on "How the Department of Commerce Can Serve the Chemical Industry."

Brigadier-General Amos A. Fries, Chief of the Chemical Warfare Service of the U. S. Army, will attend the exposition and speak on Tuesday evening, Sept. 12, taking for his topic the peace time application of chemical warfare gases in the extermination of forest and farm pests, with comment on other uses of these toxic gases.

Separate auditoriums for the motion picture program and for the speakers at the 1922 Chemical Exposition are to be built on the fourth floor of the Grand Central Palace. Owing to the big program this year, it has been deemed advisable to double the auditorium facilities, separating the motion pictures from the balance of the program.

The standardization program of the 1922 Chemical Exposition, composed of a number of addresses on standardization by well-known authorities, will be held on Friday, Sept. 15, under the direction of the New York Section of the American Chemical Society. Dr. Martin H. Ittner will act as chairman.

Excellent Program for Ceramic Meeting

American Ceramic Society Plans "Ceramic Day" at Chemical Exposition

The American Ceramic Society has provided the program for one of the days during exposition week known as Ceramic Day. This will be on Friday, Sept. 15. President Frank H. Riddle will appear on the opening program of the exposition with the presidents of other technical societies. E. P. Poste and Ross C. Purdy will appear on the special program on "Specifications." Mr. Poste will discuss specifications for enameled chemical ware and Mr. Purdy will describe the problems in writing specifications for refractories.

The partial program follows:

High-Temperature Cements, by W. H. Gaylord, Jr., Quigley Furnace Specialties Co.

Application of Magnetic Separator in Ceramic Industries, by E. S. Hirschberg, Dings Magnetic Separator Co.

Preparation of Clays and Minerals for Ceramic Purposes, by G. D. Dickey, chemist, Industrial Filtration Corporation.

Apparatus for Quickly Determining Fineness of Grind, by Eric Turner, Trenton Flint & Spar Co.

Feldspar Colloquium: W. H. Landers, George M. Darby, O. O. Bowman, 2nd, V. A. Staudt, C. R. Moore, C. M. Franzheim and others.

Manufacture of Gray Enameled Ware, by H. C. Arnold.

Whiting for Ceramic Uses, by A. E. Williams.

Gas Producers for Glass Works, by C. B. Chapman, Chapman Engineering Co.

Witchery of Glazes, by Paul E. Cox.

Architectural Faience and Its Artistic Possibilities, by Conrad Dressler.

Organization of a Decorative Ceramic Research Department; Financial and Manufacturing Considerations, by Frederick H. Rhead.

Electrochemical Society Program

(Continued from page 515)

C. B. Gibson: Electric Annealing of Malleable Iron.

P. S. Gregory: Electric Steam Generators and Their Application.

J. Murray Weed: A New Type of Induction Furnace.

A. Glynne Lobley: A Simple Electric Crucible Furnace for Melting Aluminum.

2 p.m. Reading and Discussion of Papers.

A. E. R. Westman: The Relation Between Current, Voltage and the Length of Carbon Arcs.

George A. Richter: Manufacture of Carbon Bisulphide.

O. C. Ralston: Electrosmosis and Electrophoresis. Two Definitions.

Alexander Lowy and Catherine M. Moore: Electrolytic Oxidation of Isoeugenol.

Alexander Lowy and Henry S. Frank: Electrolytic and Chemical Chlorination of Benzene.

C. W. Vinal and L. M. Ritchie: A New Method for Determining the Rate of Sulphation of Storage Battery Plates.

F. C. Mathers and Jacob W. H. Aldred: Preparation of Perchlorates by Heating Chlorates.

H. C. P. Weber: Changes in the Electrical Conductivity of Varnishes During Drying.

C. J. Rodman: Arc Action on Some Liquid Insulating Compounds.

S. F. Howard and T. A. Martin: The Difference Between the Half Sum and the Square Root of the Product When Weighing by the Method of Gauss.

The excursion train to Shawinigan Falls leaves Montreal at 11:30 p.m. and will return Saturday evening in ample time to permit members wishing to make connections for all through night trains home.

A.I.C.E. to Banquet During Exposition Week

The American Institute of Chemical Engineers will hold its usual banquet during exposition week on Thursday, Sept. 14, at the Hotel Pennsylvania at 6.30 p.m. This dinner has become quite a feature of exposition week and Institute members make plans to visit the exposition so as to be there at that time. Ladies are invited to attend the dinner.

Reservations may be made by writing to the secretary, Dr. J. C. Olsen, the Polytechnic Institute, Brooklyn. They may also be made at the desk of the Chemists' Club and at the *Chem. & Met.* booth (No. 42) at the Chemical Exposition, which will be used as the headquarters of the Institute. Those desiring to attend are urged to make reservation beforehand if possible.

Chemical Exposition Exhibitors Requested to File Catalogs

Under the direction of W. T. Read of the department of chemistry, Yale University, students in the industrial and engineering chemistry course will spend the week of Sept. 11 at the Chemical Exposition in Grand Central Palace, New York. This is the third successive year that Professor Read has brought his students to the exposition. As the supply of catalogs in his department is now out of date, he requests that exhibitors file with the exposition management ten copies of their catalogs and trade literature for the use of his students. The catalogs will not only be used at the exposition but will be filed in the library of the chemical department at Yale University.

Personal

C. C. Concannon, a Harvard chemist of the class of 1911, has been appointed assistant chief of the Chemical Division, Bureau of Foreign and Domestic Commerce. Mr. Concannon since 1916 has been connected with Takamine, Inc., and is thoroughly experienced in the details of chemical importing and exporting.

Prof. Robert T. Haslam has been appointed director of the research laboratory of applied chemistry, Massachusetts Institute of Technology, to succeed Robert E. Wilson, who has resigned. Professor Haslam has been for some time in charge of the Institute's school of chemical engineering practice.

Dr. Simon Klosky has accepted an appointment as instructor at the Martin Maloney Chemical Laboratory of the Catholic University of America. Dr. Klosky served overseas as First Lieutenant in the Air Service during the World War and is now with the research department of Edgewood Arsenal, Chemical Warfare Service.

Walter B. Land has been appointed geologic aid to take the place of H. W. Hoots in the work on Texas potash. Mr. Lang will be in the chemical laboratory of the U. S. Geological Survey for a short time prior to taking up the work in Texas.

George Walker, formerly of the Dorr Co., is now with the Grasselli Chemical Co., Cleveland, Ohio, in the research department.

Dr. George B. Waterhouse, for the past 16 years connected with the Lackawanna Steel Co., Buffalo, N. Y., has accepted the appointment as head of the department of metallurgy at the Massachusetts Institute of Technology, Boston, Mass. He will assume his new duties at the beginning of the college year this fall. Dr. Waterhouse succeeds Prof. H. O. Hofman, who resigned last June as head of the department at the Boston institution, after many years of service.

Thomas H. Wickenden and Charles McKnight, Jr., have recently joined the development and research department of the International Nickel Co., New York City, to undertake development work in connection with alloy steels. Mr. Wickenden was for many years associated with the Studebaker Corporation as engineer in charge at its South Bend plant, and more recently associated with the Zeder-Skelton-Breer Engineering Co. in a consulting capacity. Mr. McKnight was formerly works manager of the Carbon Steel Co. and engaged for many years in the production of alloy steels.

Robert E. Wilson has resigned as director of the research laboratory of applied chemistry, Massachusetts Institute of Technology, to accept a position on the research staff of the Standard Oil Co. of Indiana.

The American Society for Steel Treating has elected the following new officers: President, T. D. Lynch, research engineer, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.; second vice-president, W. S. Bidle, president, W. S. Bidle Co., Cleveland, Ohio; secretary, W. H. Eisenman, 4600 Prospect Ave., Cleveland, Ohio; director, S. M. Havens, assistant treasurer and manager, Ingalls-Shepard Division, Wyman Gordon Co., Harvey, Ill. The board of directors of the American Society for Steel Treating will be composed of the newly elected officiers and the following: First vice-president, R. J. Allen, metallurgist, Rolls-Royce Co. of America, Springfield, Mass.; treasurer, J. V. Emmons, metallurgist, Cleveland Twist Drill Co., Cleveland, Ohio; director, J. J. Crowe, metallurgist, Philadelphia Navy Yard, Philadelphia, Pa.; director, A. E. White, past president, director engineering research, University of Michigan, Ann Arbor, Mich.; director, F. P. Gilligan, past president, secretary-treasurer, Henry Souther Engineering Co., Hartford, Conn. The new officers will begin their duties at the close of the annual convention of the society, which will be held at Detroit Oct. 2 to 7 at the same time as the International Steel Exposition.

Obituary

T. R. L. Loud, vice-president and general manager of the New York Quinine & Chemical Works, Inc., New York, died Aug. 19, as the result of an automobile accident near Trenton, N. J., while en route to Atlantic City. He was associated with the chemical and drug industries for the past 50 years, and at one time was connected with the Mallinckrodt Chemical Works, St. Louis, and later with the Herf & Frerichs Chemical Co. of the same city. He was 64 years of age at the time of his death.

Paul F. McGovern, New York manager for the General Alloys Co. and for years the representative of the Quigley Furnace Specialties Co., died almost instantly from an acute heart attack, Aug. 12, 1922.

Charles Scott, Jr., of Philadelphia, vice-president of the Giant Portland Cement Co. and a director of the Railway Steel Spring Co., died at Glouces-ter, Mass., Aug. 21.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

The Outlook for Better Business

A Survey of Fundamental Economic Conditions Indicates That Once Present Difficulties Are Surmounted, Substantial Business Revival Is Assured

ANY REVIEWER of bu iness conditions must be impressed by the fact that two well-defined, but distinctly opposing, forces are largely responsible for the present situation. His problem in properly evaluating these forces must necessarily involve a consideration of whether their effects are temporary and subject to change either for better or worse or are the result of some fundamental economic movement having a permanent bearing on business progress.

It must be admitted that the labor troubles in the coal fields and on the railroads are of grave significance to industry and at the present moment appear to exert far-reaching effects on industrial activity. Production has been seriously curtailed. Although many industries have suffered and probably will continue to suffer, business refuses to regard the strikes as a permanent blight on the progress toward general prosperity. The ground gained during the past year will not be given up easily. Confidence in the soundness of the underlying situation has not been materially disturbed and there is a widespread conviction that once the difficulties of transportation and fuel supplies are definitely settled, there will be no further obstacles to substantial business revival.

Higher Security Values

This very evidently is the sober judgment of the investing public. Security values have continued at high levels. New records have been set by representative stocks and bonds. The *Wall Street Journal's* average for twenty industrials was 100.75 on Aug. 30, as compared with 92.3 for July 1 and 78.59 for Jan. 10, 1922. The average for the twenty rails has risen from 73.48 for Jan. 3, 1922, to 92.68 for Aug. 30. The Dow-Jones monthly bond index for July reached 75.44, the highest point for several years.

Other fundamental business factors to show improvement in recent months include the decreasing volume of unemployment, the better adjustment of commodity prices, increasing outlook for farm products, increasing car loadings in spite of the shopmen's strike and finally the promise of an early settlement—whether to everybody's satisfaction or not—of the uncertainties of the new tariff bill.

Less Unemployment and Higher Wages

Encouraging news of employment comes from all sections of the country. Reports from sixty-five cities showed that on July 31 1,428 concerns were employing 1,729,085 workers—a gain of 7,434 over the payrolls of June 30. Of these industrial centers, forty-four (mostly in New England and along the Atlantic seaboard) reported increases and twenty-one reported decreases. The Department of Labor's monthly survey of labor conditions by industries shows that in twelve manufacturing industries there were seven increases in employment and five decreases during the month of July. The largest increase, 44.8 per cent, was in the iron and steel industries, while cotton manufacturing showed the largest decrease, 26.4 per cent. Furthermore there have been many significant wage advances, particularly the 20 per cent increase announced by the Steel Corporation and followed by other steel companies. The New York Federal Reserve Bank's index of wages for July was 66 per cent above the 1914 level. Wage increases at this time would seem to confirm the belief that the recent industrial progress has been of a substantial character.

Car loadings of revenue freight had fallen from a weekly average of 351,700 cars in June to 828,029 for July, but the first 3 weeks of August showed a striking recovery to 853,383 cars. In the week ended Aug. 19, 856,219 cars were loaded—an increase of 3,639 cars over the preceding week and of 41,072 over the corresponding week in 1921. The decreases noted in earlier months were due almost entirely to the lower coal loadings.

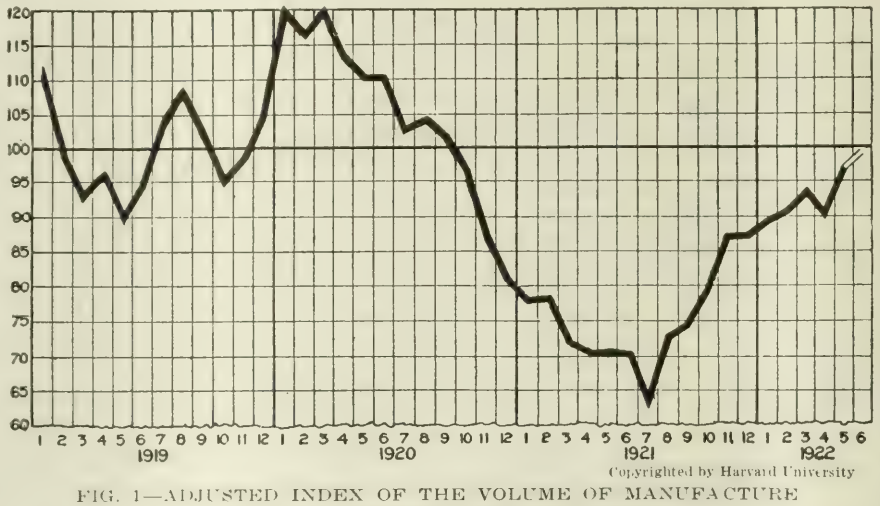


FIG. 1—ADJUSTED INDEX OF THE VOLUME OF MANUFACTURE FOR THE PRINCIPAL BASIC MATERIALS

(*Normal = 100*)

Progress in the Basic Industries

The Harvard Economic Service's index of the volume of manufacture is based on a combination of three minor indices: (1) Basic materials, (2) pig iron for equipment, vehicles, etc., and (3) consumption goods. The index of basic materials, whose trend since 1919 is shown in Fig. 1, includes iron and steel, lumber, cotton and woolen fabrics, leather and paper. This index stood in June at 99.0, the highest figure recorded since September, 1920. Except for a slight recession in April, this index has shown a consistent upward movement ever since July, 1921. Seasonal influences

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	150.60
Last week	149.80
September, 1921	147
September, 1920	267
April, 1918 (high)	286
April, 1921 (low)	140

Three of the twenty-five commodities included in this index were advanced during the past week and there were no reductions. Ammonium sulphate, bleaching powder and linseed oil were reported at slightly higher levels.

have been such, however, that July, 1922, will probably again show a slight recession.

The output of pig iron recorded a slight increase in July—from 2,361,000 long tons in June to 2,400,000 tons in July. Steel ingot production, however, fell from 3,012,000 tons to 2,843,000 tons during this same period. Unfilled orders on the books of the U. S. Steel Corporation showed a gain of 140,630 tons over the previous month.

Pulp and paper production continues at a better-than-average rate. The total output of all grades of newsprint during July, 1922, was 120,839 net tons, while only 94,247 tons was produced in July, 1921, and the 5-year average for the month is 110,000 tons. Wood-pulp production in July, 1922, was 279,308 net tons, a gain of 101,000 tons over July, 1921, and well above the average of 270,850 tons for July, 1919-1922.

Higher prices and a record volume of sales for both foreign and domestic consumption have stimulated the leather industry. Shoe manufacturers are laying in large stocks in anticipation of an unusually good fall trade. Production, especially of sole leather, increased considerably in both June and July. August figures are not yet available, but it is believed that the increased rate has been well maintained.

The American Petroleum Institute estimated the daily average production of crude oil at 1,504,150 bbl. for the week ended Aug. 13. This is a gain of 5,050 bbl. over the average for the preceding week, the largest for any month of 1922.

Heavy Chemical Situation

Manufacturers of heavy chemicals in Philadelphia and vicinity have reported to the Federal Reserve Bank of that district that they can accept no more orders on account of the impending shortage of fuel. At the present time these industries are running at about 80 per cent of capacity, but in most plants the stocks of coal are slight and there is every prospect for seriously curtailing production within the near future.

In the 12 months ended June 30, 1922, exports of all chemicals fell off about 50 per cent, but the foreign shipments of heavy chemicals recorded gains in both volume and value. Exports of acetate of lime and of glycerine doubled, while caustic soda, borax and sodium silicate showed heavy gains. Bleaching powder and soda ash declined.

In general credit conditions are reported as only fair. In proportion to the volume of sales, the accounts outstanding for July have increased from 130.4 per cent in June to 137.5 per cent for July.

Atlas Dividend

A special dividend of 3 per cent on the common stock of the Atlas Powder Co. has been declared, payable Sept. 11, 1922, to stockholders of record at the close of business on Aug. 31, 1922. The stock transfer books will not be closed for the payment of this dividend.

Credit Conditions in the Fertilizer Market

Accompanying the annual report of the American Agricultural Chemical Co. is a statement by the chairman of its board, Robert S. Bradley, which gives a very encouraging view on the fertilizer outlook. Although the demand has not yet returned to normal, there is every prospect for such a return within the near future. Mr. Bradley's statement in part is as follows:

> The sales of fertilizers in the United States for the past year are estimated to have been about 65 per cent of the tonnage of 1920; but while the demand has thus decreased, owing to the severe depression in all agricultural districts during the past 2 years, the productive capacity of the fertilizer industry had been considerably increased under the stimulus of the heavy demand in the spring of 1920. These conditions have naturally led to very severe competition and to a continuance of low prices.
>
> Although there still remains uncollected in the South a large amount of fertilizer notes and accounts from sales of 1920 and 1921, it is estimated, nevertheless, that one-half of all the fertilizer used in the cotton belt in the spring of 1922 was sold for cash, instead of on the usual fall credit terms, and it is confidently expected that the balance of these sales will be collected this fall at maturity, together with a large part of the receivables carried over from 1920 and 1921. Much more fertilizer could have been sold in the South last spring had it not been for the unsatisfactory credit conditions prevailing in that section. From June, 1921, to June, 1922, the price of cotton advanced from around 11 cents per pound to over 22 cents, which latter price should yield a very satisfactory profit on the present cost of production. If the price of cotton should remain around present figures there should be a considerable increase in the demand for fertilizers in the Southern States in the spring of 1923.
>
> In the Northern States credit conditions have been more favorable and a relatively larger tonnage of fertilizer has been sold, though far less than in 1920. Competition in these states has been very keen and prices have remained at a low level.

The annual statement of the American Agricultural Chemical Co. and its associated companies shows a net operating deficit for the year ended June 30, 1922, of $1,124,070.56.

Du Pont Earnings in 1922

For the 6 months ended June 30, 1922, E. I. du Pont de Nemours & Co. reports net earnings of $5,346,857 after deducting all expenses, taxes, depreciation, etc. When provision had been made for $1,403,653 of bond interest and discount, and $2,137,791 for debenture stock dividends, there remained $1,805,412 available for the common stock. This was equivalent to $2.85 a share for the six-month period.

Mathieson Alkali Turn Loss Into Profit

The Mathieson Alkali Works, Inc., operated during the second quarter of 1922 at a net profit of $233,898 as compared with a loss of $361,252 for the corresponding period of last year. The gross earnings were $369,489, from which $135,591 was set aside for depreciation reserves. Payment of preferred stock dividends has been resumed, and it is estimated that after allowances have been made for federal taxes, preferred dividends, sinking fund, etc., the earnings on the common stock will be at the rate of 9.7 per cent per annum.

The New York Market

New York, Sept. 3, 1922.

Activity in the chemical market during the past week has been along broader lines than at any other time for a considerable period. Consumers are showing lively interest in many of the basic commodities. Spot stocks have dwindled considerably and an eager desire to cover has been stimulated by the fear of delayed shipments resulting from the rail and coal strikes. Reports from abroad show that quotations on leading chemicals are much higher than at any time this year. The coal strike in many instances has restricted adequate production and has given the resale merchant an opportunity to get rid of any surplus stocks. Prices on many important items have already advanced and consumers are somewhat uneasy about the chances of obtaining additional supplies. Many are of the opinion that the market shows every sign of broadening materially on an upward basis.

One of the items that commanded the most interest was bleaching powder. Supplies have been taken so quickly that leading producers are unable at present to quote anything but October-November shipments. The alkali situation still remains in an extremely firm position both for home and export consumption. White powdered arsenic has again been advanced by importers and has given rise to keen speculation among resale merchants. Nitrite of soda, prussiate of soda, permanganate of potash, prussiate of potash and oxalic acid have shown considerable activity during the interval.

General and Special Chemicals

Acetate of Soda—Spot supplies are exceedingly low, with production limited to contract specifications. The recent strength in acetate of lime, as well as the higher labor costs, is directly the cause for the advance. Quotations ranged around 7¼c. per lb. for small quantities.

Alums—A moderate consuming business is reported for the lump ammonia alum at 3¼@3½c. per lb. Imported potash alum has been offered down to 3c. per lb.

Aluminum Sulphate—Domestic producers are experiencing a steady call for the commercial grade at 1½c. per lb. Sales of iron-free are reported at 2½c. per lb. The general tone is steady.

Amyl Acetate—Prices are recorded at higher levels and the market presents a steady position. Offerings are rather light, while consumers have shown a better interest for additional supplies. Prices range from $2.25 per gal. upward, depending upon the seller and quantity.

Arsenic—The market remains exceedingly firm, with quantity lots very difficult to obtain either on spot or for prompt shipment. During the later trading prices were advanced to 8½@9c. per pound.

Bleaching Powder—This item has been the feature of the week's trading. Supplies on spot and nearby shipments

have practically been exhausted. Leading factors quote odd lots at $1.90 per 100 lb. ex-store and $2 per 100 lb. for Oct.-Nov. shipment, f.o.b. works.

Fusel Oil—Crude material is moving on the basis of $1.55 per gal., which is somewhat higher than recently quoted. The refined material is also higher, with sellers asking $2.75 per gal. Business is running along regular lines and leading producers seem satisfied with the volume of passing business.

Nitrite of Soda—Large importers and traders have announced an advance on all available spot goods and material for shipment. Higher prices abroad and the scarcity of material for immediate consumption are responsible for the keen interest and renewed speculation. A few odd lots on spot were offered up to 8½c. per lb.

Oxalic Acid—Prices continue to follow an upward course. Buying interest has not ceased and the general tone is very satisfactory. Prices range from 16¾@18½c. per lb., depending upon the seller and quantity.

Prussiate of Potash—Yellow material has been materially advanced during the interval and prices were quoted very firm at 35c. per lb. for small lots. The red variety was quoted higher at 95c.@$1 per pound.

Prussiate of Soda—Activity has increased notably and the tendency of prices has been distinctly higher. Sales were reported for moderate quantities up to 23c. per lb., an advance of 3c. per lb., since our last report.

Coal-Tar Products

Crude coal-tar products have shown considerable strength. It is apparent that the coal and rail situation is directly responsible for the restricted production in some of the these basic commodities, and leading factors are of the opinion that this will eventually force up values of intermediates. The present condition of the market has permitted resale merchants to rid themselves of any surplus stocks. The shortage in phenol is very acute and prices are rising to extremely high levels. Salicylic acids have been affected by this and prices have been advanced.

Benzene—The restricted offerings have placed the spot market in a very strong position. Factors are having trouble in making shipments on old contracts. Future orders are the only transactions being considered. Quotations at the works are firm at 27@32c. per gal. for the 90 per cent and 30 @35c. per gal. for water white.

Cresylic Acid—The market is in a very firm state. The continued inquiries and scant offerings are keeping the market at its present high levels. Domestic offerings for shipment are quoted around 51@53c. per gal. for the 95 per cent and 56@58c. per gal. for the 97@99 per cent. Imported material is quoted at 64@65c. per gallon.

Phenol—There has been a pronounced scarcity of spot material and prices have been sharply advanced. Quotations for odd lots are heard around 23c. per pound.

The Chicago Market

CHICAGO, ILL., Aug. 29, 1922.

The tone of the industrial chemical market has been firmer during the past 2 weeks. A good volume of business was reported from nearly all quarters, particularly from first hands, for there appears to be a growing tendency on the part of the buyer to purchase his supplies from the manufacturer. There were but few price advances to be noted, although nearly all items were in a very firm position. Imported chemicals in particular were exceptionally firm, as holders had little or no idea of their replacement costs. It was to be noticed that most buyers were willing to pay a small premium for domestic goods.

General Chemicals

Caustic soda was very firm, with only moderate supplies available. Solid 76 per cent material was available in small or moderate lots at $3.85@$4 per 100 lb. and the ground or flake at $4.40 @$4.50. *Caustic potash* was unchanged as to price and was reported to be moving fairly well at 6½@7c. per lb. for the 88-92 per cent material. *Soda ash* continued to move in a good volume and was unchanged at $2.35 per 100 lb. for small lots of 58 per cent material in cooperage. *Sal soda* enjoyed a good inquiry and was available at $1.90 per 100 pounds.

The list of alums was rather quiet, with moderate supplies available. Lump *potash alum*, iron free, was offered at 4½@5c. per lb. in single-bbl. lots and the powdered at 6@6½c. *Sal ammoniac* was quite firm, with first hands in control of the situation. White granular material of domestic manufacture was quoted at 7¾c. per lb. in moderate quantities. *White arsenic* maintained its firm position and was offered at 8½@9c. per lb. *Barium carbonate* was in a firm position and small lots for spot delivery were held at 5c. per lb. The situation on *copper sulphate* was less acute and moderate lots were available at 6½c. per lb. *Carbon bisulphide* was quite firm, with only small quantities available at 7@7½c. per lb. *Carbon tetrachloride* was in about the same position as before and was quoted at 9½@10c. per lb. in large drums. *Glycerine* was in a very firm position with most of the refiners asking 17c. per lb. for the c.p. material in drums. *Formaldehyde* was unchanged both as to price and demand. Supplies were available at 9c. per lb. in single-bbl. lots. *Furfural* was unchanged at 35c. per lb. for 1,000-lb. lots. *Lead acetate* was in no better demand and barrels were offered at 11@12c. per lb. for the white crystals. *Red phosphorus* was very quiet, with imported material offered at 26c. per lb. and domestic at 48c. *Phosphorus pentoxide* was in better demand and was quoted by the one holder at 35c. per pound.

A better demand was to be noticed for bichromates, the coal situation forcing the price upward. *Potassium bichromate* was quoted at 11½@12c. per lb. and soda at 9@9½c. *Potassium chlorate* was very firm and scarce on spot, small lots of the crystals bringing 10c. per lb. *Potassium permanganate* was reported to be in a firm position with supplies getting scarce. Spot U.S.P. crystals were held at 16½c. per lb. and the movement was said to be very fair. *Hyposulphite* of soda was unchanged in price and moved in a routine way at $3.85 per 100 lb. for pea crystals in barrels.

Linseed Oil and Turpentine

Linseed oil was reported to be moving in a fair volume but the price was weak at 92c. per gal. for 5-drum lots of the boiled and 90c. for similar quantities of the raw.

Turpentine was also moving in a fair way, but factors differed on the condition of the market with some predicting a sharp decline, others an advance. Five-drum lots were quoted at the close of today's market at $1.23¾ per gallon.

The Iron and Steel Market

PITTSBURGH, Sept. 1, 1922.

A fundamental change has occurred in the past fortnight in the spirit that underlies the iron and steel market. Previously there had been a gradual but very moderate departure from the policy well outlined last June, of holding prices down so as to avoid discouraging buyers for deliveries in the late months of the year, as it grew clearer that on account of curtailed production there would be little to sell. The new thought is that the astonishing and complete success of the coal miners in their strike, with various other developments, makes inflation unavoidable and that in the circumstances no general benefit can accrue from efforts to hold prices down. Banking interests appear to have been the first to sense the situation and to have passed the word around that since labor forces inflation the best course is to let inflation have its way, producing its natural economic consequences, resulting eventually in people in general becoming less extravagant and more willing to work.

The result is that the influences that are usually exerted to prevent a runaway market are not operative. Prices are not going to be pushed up by design, but they are going to be permitted to go up if so disposed—as they are.

Predictions are already being made that "the inflation can't last long," April 1 being sometimes mentioned as an extreme date. The assigned period may easily prove too short. Business has momentum. Not all material still to be received by buyers is at high prices, for in practically all lines of commerce there are forward commitments. Costs of production do not instantly mount when the current market advances. Furthermore, it is being remarked that some bankers have said that "there is too much money" for prices and wages to be held to reasonable levels, in keeping with economic laws, but if that is the case the large amount of money cannot be spent in a short space of time.

The iron and steel industry appears to have assumed that since it has had

nearly 2 years of very lean times and in the past few months production costs quite out of keeping with prices at which the steel made had been sold, it should now make the most of the present opportunity.

Steel Prices Advancing

As reported under date of Aug. 18, the Steel Corporation advanced its sheet prices $2 a ton on blue annealed and $4 a ton on other descriptions, following advances previously made by independents. On Aug. 23 the corporation advanced prices on welded tubular goods three points on black and two points on galvanized, a point being equivalent to about $2 a net ton, 8 days after independents had made a similar advance, and 1 day after the corporation's wage advance had been announced.

The absolute minimum on bars, shapes and plates has advanced from 1.80c. to 1.90c. in the case of bars and to 2c. in the case of shapes and plates, this being for altogether indefinite delivery. The ordinary market is 2.25c., while prompt plates have been bringing 2.50c. for 2 or 3 weeks' delivery. While the Steel Corporation has made no formal announcement as to prices of wire products, it is selling at prices as recently advanced by independents, the advance being $2 a ton on plain wire to 2.35c. and 20c. on a keg of nails to $2.60.

The Steel Corporation on Aug. 22 announced that, effective Sept. 1, it would advance wages generally by 20 per cent. This would raise the common labor rate from 30 to 36 cents an hour. Some of the independents followed instantly, others later. Wages in the Connellsville region were dealt with separately, as will be indicated later. The general wage advance increases the cost of making the average net ton of finished steel by something like $4, the Connellsville wage advance adding something like a dollar more.

On Aug. 22, after the "Cleveland agreement" in the union bituminous coal industry, the H. C. Frick Coke Co. posted notices in the Connellsville region restoring the wage scale of Sept. 1, 1920, the highest scale ever paid in the region, an exception being the rate for outside day labor, which was made to conform to the labor rate at mills and furnaces. The advance was to be effective Aug. 23 and strikers were invited to return to work. Independent operators followed the Frick scale. While some men have returned, the expected stampede has not occurred. This week the Pittsburgh district operators signed the scale and it is a question whether this will affect the Connellsville labor situation favorably or otherwise. The Connellsville region has been non-union for at least 30 years and while the coal strike has presented many surprises, it is inconceivable that the Connellsville operators will sign any agreement.

Connellsville coal and coke prices have been declining, steam coal having reached a range of $4.50@$5, while furnace coke is $10@$11 and foundry coke $13@$14. Blast furnaces are beginning to take hold in a very limited way, the supply offered being very scant and the price still distinctly objectionable. One of the Shenango furnaces resumes this week, on purchases of odd lots of coke, but this is to make bessemer iron, supplied molten on a long term contract to an ingot mold foundry. There is practically no merchant pig iron production in western Pennsylvania and the valleys. The last foundry iron appears to have been sold some time ago, and recourse has been had to Buffalo, where a purchase has just been made of several hundred tons of prompt iron at $34 Buffalo for Pittsburgh delivery, the valley equivalent, considering freights, being $35.50. Bessemer is up to $32 valley on small-lot sales. Basic cannot be had at under $30 valley, and probably not at that figure. The only pig-iron market is a spot or prompt market, forward deliveries being out of the reckoning. When it becomes possible to offer forward deliveries, the expected readjustment in prices may not occur, the resumption being so gradual as to make forward prices in line with the spot market then existing.

Soft steel bands	3.10	3.20
Plates, ¼ to 1 in. thick	2.70	2.70

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

PAPER—The Lititz Box Board & Paper Co., Eden, near Lancaster, Pa., has adopted a 24-hour daily working schedule at its plant, under a 7-day operating basis, giving employment to a large working force. It is said that orders on hand insure this capacity for some time to come.

The H. H. Bartin & Son Co., Philadelphia, Pa., manufacturer of sandpaper, is operating on a full-time schedule at its plant, giving employment to a regular working force. The company is now building a 2-story addition, and will place the structure in service at the earliest possible date.

The Tonawanda Board & Paper Co., Goose Island, Tonawanda, N. Y., heretofore operated by the Beaverboard Companies, Buffalo, and recently acquired by new interests, is planning for the immediate resumption of production at the mill, which has been closed down for about 2 years past. The new company is headed by Maurice W. Simon, Buffalo.

The Temiskaming Pulp & Paper Co., Haileyburg, Ont., will commence operations at once at its new local mill, recently completed at a cost of about $1,000,000, giving employment to a large working force. Initial production will be increased gradually until the plant capacity of 40 tons per day, ground-wood pulp, is reached.

The Jesperson Newsprint Co. has reopened the former Perseverance Paper Mill, South Union St., Lambertville, N. J., recently acquired, following considerable rebuilding and remodeling. The plant will manufacture newsprint paper under a new process, and will operate at a capacity basis. Henry Weeks is general manager.

LEATHER—The Benz Kid Co., Lynn, Mass., is increasing operations at its tannery and is now manufacturing at the rate of about 1,000 dozen skins daily.

The Graton & Knight Mfg. Co., Worcester, Mass., has advanced production at its tannery at St. Louis, Mo., to about 75 per cent of normal. At the local finished leather plant at Worcester, the working force has been increased from 700 to 1,200 persons.

IRON AND STEEL—The steel mill of the Driscoll-Reese Co., Hamburg, Pa., closed for a number of months past, has been acquired by new interests and will be placed in operation at once. The machinery will be repaired and additional equipment installed. A new company will be formed to run the mill.

The Eddystone Steel Co., Eddystone, Pa., has closed its plant temporarily owing to fuel shortage. The plant has been giving employment to about 200 men.

The Tacony Steel Co., Tacony, Philadelphia, Pa., is operating at full capacity at its rolling mills and at close to 50 per cent output in other departments of the works. The company has recently changed two of its four furnaces to utilize oil as fuel.

The Youngstown Sheet & Tube Co., Youngstown, O., is increasing production at its local bessemer plant, following a resumption of operations recently curtailed on account of fuel shortage. One of the bar mills at the works is in service, running at full capacity.

The Eastern Steel Co., Pottstown, Pa., will make immediate repairs in its No. 1 blast furnace, and will place the unit in operation as soon as sufficient fuel is available. The No. 2 blast furnace of the company has recently been blown out owing to a shortage of coke.

The National Enameling & Stamping Co. is increasing production at its sheet mills at Granite City, Ill., following a curtailment due to fuel shortage. Arrangements have been made to use oil as fuel in a number of departments. It is planned to develop maximum output at the earliest possible date. The plant is said to be about to open behind on orders.

The American Steel & Wire Co., Youngstown, O., has been forced to reduce operations to a point of about 25 per cent of normal, owing to coal and coke shortage.

The Republic Iron & Steel Co., Youngstown, O., has resumed operations at four of its bar mills, following a recent curtailment. Arrangements are being made to increase the finishing mill capacity at the works.

The Eastern Rolling Mills Co., Baltimore, Md., has adopted a 24-hour day working basis at its plant, for the production of steel sheets, and up to the present time the plant has not felt the effects of fuel shortage. Employment is being given to about 1,200 men, and it is said that this working force will be advanced at an early date.

Owing to coal and coke shortage, the Carnegie Steel Co. has suspended operations at five of its seventeen bar mills in the Youngstown, O., district.

The Kokomo Steel & Wire Co., Kokomo, Ind., is curtailing operations at its mills, owing to fuel shortage.

The Central Coal & Iron Co., Birmingham, Ala., has its blast furnace at Holt, Ala., ready to blow in, and will place the unit in service as soon as the fuel situation has improved.

METALS — The New Jersey Zinc Co., Palmerton, Pa., is increasing operations at its plant and practically all departments are now running on full time with full working force. New employees will be added gradually.

The Butte Copper & Zinc Co., Butte, Mont., has resumed operations at its local Emma properties, which have been closed down since early in 1921. It is expected to reach normal production within a few weeks.

MISCELLANEOUS — E. I. du Pont de Nemours & Co., Wilmington, Del., will reopen its Ashburn works at Hannibal, Mo., devoted to the manufacture of high explosives, early in September, following a shutdown for more than a year.

The Industrial Alcohol Co., Baltimore, Md., is increasing production at its Curtis Bay plant to 100 per cent capacity, for the first time in a number of months. Operations at all other plants of the company are being developed to maximum output.

The Lehigh Portland Cement Co. has curtailed operations in a number of departments at its three mills at New Castle, Pa., owing to a strike of laborers. The men have asked for a 25 per cent wage advance.

The American Tar Products Co., Woodward, Ala., is maintaining active production at its local plant with normal working force. The company has adopted a plan for using pulverized pitch as fuel instead of coal.

The L. Martin Co., Philadelphia, Pa., manufacturer of carbon and lampblack products, has advanced production to full capacity. At this time last year the works were running at about 50 per cent of normal. It is said that orders on hand insure maximum output for some time to come.

The Pure Oil Co., Columbus, O., operating refineries in Pennsylvania, West Virginia, Minnesota, Ohio and Oklahoma, has increased production at the plants to a basis of 30,000 bbl. a day, gross.

The United States Navy Department is arranging for the resumption of operations at its helium gas plant, Fort Worth, Tex., early in September, when an appropriation of $800,000, recently granted by Congress, will become available. It is expected to develop 8,000,000 cu.ft. of helium gas for government use during the coming year.

Capital Increases, Etc.

THE AMERICAN HARD WALL PLASTER CO., Utica, N. Y., has filed notice of increase in capital from $25,000 to $350,000, for proposed expansion.

THE KANAK CO., New York, N. Y., has been organized with a capital of $100,000, to form a consolidation of the Kanak Co., 708 6th Ave., New York, and the Deode Chemical Co. The new company will manufacture chemical specialties, with headquarters at the address noted. It is headed by H. J. Davenport, K. Burham and F. S. Metcalf.

THE MESABI IRON CO., 25 Broad St., New York, N. Y., operating iron ore properties and milling plant for the manufacture of iron ore concentrate, etc., is disposing of a stock issue of $600,000, a portion of the proceeds to be used for expansion.

THE OHIO REFINING CO., Louisville, Ky., a Delaware incorporation, manufacturer of refined petroleum products, has filed notice of increase in capital from $500,000 to $2,000,000, for proposed expansion.

THE ROCHESTER BRICK & TILE MFG. CO., Rochester, N. Y., has filed notice of reduction in capital from $84,000 to $24,000.

THE DOMESTIC COKE CORP., Fairmont, W. Va., has filed notice of increase in capital from $3,500,000 to $4,500,000, for proposed expansion.

THE ILLINOIS POWDER MFG. CO., 28 East Jackson Blvd., Chicago, Ill., has filed notice of increase in capital from $250,000 to $500,000.

THE ALBRECHT-HERD CO., Equitable Bldg., Baltimore, Md., manufacturer of salt products, has filed notice of increase in capital to $300,000.

THE ARMSTRONG CORK CO., 24th St., Pittsburgh, Pa., manufacturer of cork insulation products, etc., is arranging for an increase in capital from $17,000,000 to $30,000,000.

THE UNITED STATES GLASS CO., South 9th and Bingham Sts., Pittsburgh, Pa., has called a special meeting of stockholders on Oct. 4 to vote on a proposition to dispose of the plant and property of the company for a consideration of $1,920,000. Ernst Nickel is secretary.

THE WEST INDIA SUGAR FINANCE CORP., 129 Front St., New York, N. Y., is arranging for an increase of $835,000 in preferred stock, the proceeds to be used in connection with extensions in operations of its sugar properties in the West Indies and to provide for the merger of other sugar refineries in this district.

Construction and Operation

Arkansas

FORT SMITH—The Industrial Laboratories, North 1st St., manufacturers of floor-sweeping compounds, cleansers, etc., are planning for the immediate rebuilding of the portion of their plant, recently destroyed by fire, with loss estimated at about $18,000. W. V. Botright is head.

GRAVETTE—The Spees Vinegar Co., Kansas City, Mo., is arranging for the immediate installation of new equipment at its plant to increase the present capacity.

California

LONG BEACH — Alexander Hursh, 12 Locust St., Los Angeles, will commence the immediate erection of a new oil refinery at Cherry and Newport Aves., with initial output of about 1,500 bbl. per day. It will cost about $60,000.

RICHMOND—The Lunning Mineral Products Co., manufacturers of paint products, pigments, etc., has preliminary plans under consideration for the rebuilding of the portion of its plant, recently destroyed by fire, with loss estimated at about $30,000.

VENTURA—The Associated Oil Co., Los Angeles, plans for extensions and improvements in its local storage and distributing plant on Figueroa St., estimated to cost about $30,000.

Connecticut

BRIDGEPORT — The Sieman Hard Rubber Corp. has filed plans for the construction of a new 1-story plant addition, 60x168 ft., estimated to cost about $16,000, exclusive of equipment. Work will be commenced at once.

BRIDGEPORT—The Electrolytic Iron Co., recently organized by local interests, has leased a factory at Milford, Conn., formerly occupied by Page & Nettleton, located on New Haven Ave., for the establishment of a plant for the manufacture of pure iron by the electrolysis process. The building will be remodeled and improved, and equipment installed at an early date. The works will include a complete laboratory.

BRIDGEPORT—The Compressed Paper Box Co., 128 Thompson St., recently organized with a capital of $300,000, will take over and operate the local plant and property of the company of the same name. The reorganized company plans for extensions and improvements. J. C. Stanley is president; and E. E. Irving, treasurer.

WATERBURY—The Gulf Refining Co. has preliminary plans under way for the construction of a new storage and distributing plant on South 5th St., to include a number of 1-story buildings.

Florida

MIAMI—The Pennsylvania Sugar Co., 135 South 2nd St., Philadelphia, Pa., has construction under way on the initial units of its proposed local sugar mill. The plant will have a grinding and converting capacity of 1,000 tons of sugar cane per day. It is expected to install machinery late in the fall, and have the mill ready for service early in the coming year. The company has a 100,000-acre tract in this section. George H. Earle, Jr., is president.

Georgia

LUDOWICI—The McDonald Brick Co., recently organized, has acquired the local plant of the Ludowici-Cedalon Co., heretofore devoted to the manufacture of roofing tile products. The new owner is said to be planning for extensions, to include the production of brick and other burned clay products. It will operate with a capital of $50,000.

Indiana

FAIRMOUNT—The Graham Glass Co. will make extensions and improvements in its local plant, including the installation of a new tank and other operating equipment. The works have been closed down for this purpose, and will be reopened as soon as the installation has been completed.

FAIRMONT—The Standard Oil Co. will commence the immediate construction of a new storage and distributing plant on property in the western part of the city, recently acquired. The present works in another district will be removed to the new location.

Maine

HOWLAND—The Advance Bag & Paper Co. has construction under way on a new pulp and paper mill, and plans to have the plant equipped ready for service at an early date. The machinery will be electrically operated.

Maryland

BALTIMORE—The Solarine Co., Emerson Bldg., manufacturer of metal polishes, has plans under way for the construction of a new 1-story plant, 100x150 ft., at Eagle and Mallwood Sts., estimated to cost close to $50,000, of which amount approximately $30,000 will be expended for equipment. E. H. Glidden, American Bldg., is architect. C. A. Allen is president.

HAGERSTOWN—The Security Cement & Lime Co., Equitable Bldg., Baltimore, has plans under way for enlargements in its cement-manufacturing plant at Hagerstown, to increase the capacity approximately 50 per cent. Work will be commenced at an early date.

BALTIMORE—The James Robertson Lead Works, Inc., 827 South Howard St., will commence immediately the construction of its proposed new plant addition, to comprise a 2-story building, to cost approximately $60,000. It will be equipped for the manufacture of sheet lead and other lead products. A general contract for the work has awarded recently to the Consolidated Engineering Co., Calvert Bldg. The company is a subsidiary of the United Lead Co., New York.

BALTIMORE—The Baltimore Paper Box Co., West and Howard Sts., has acquired property on the Key Highway, heretofore used by the Key Manufacturing Co., comprising a number of buildings with aggregate floor space of about 100,000 sq.ft., for a consideration of approximately $225,000. The new owner will take immediate possession and will use the plant for general manufacture. It is planned to install new machinery to cost about $75,000.

BALTIMORE — The Republic Boiler & Radiator Co., Union Ave., Woodberry, has awarded a contract to the Claiborne-Johnson Co., Garrett Bldg., Baltimore, for the construction of a 1-story foundry, 60 x 150 ft. Work will be commenced at once. William C. Keown is engineer in charge.

FUNKSTOWN—The Tanners' Hide & Tallow Co. has tentative plans under consideration for rebuilding the portion of its plant, recently destroyed by fire with loss estimated at about $25,000, including equipment.

Michigan

GRAND RAPIDS—The Grand Rapids Tire & Rubber Corp. has plans nearing completion for the construction of a new plant for the manufacture of cord tires, estimated to cost close to $250,000, with machinery. L. A. Brown is president and general manager.

FILER CITY—The Filer Fibre Co., manufacturer of kraft papers and other paper products, has awarded a contract to J. O. Olsen, Muskegon, for the construction of a new 2- and 3-story mill, 72x420 ft., with extension 60x60 ft., estimated to cost about $150,000, exclusive of equipment. Work will be placed under way at once. The company has recently disposed of a bond issue of $500,000, for general plant expansion. Philip P. Schnorbach is general manager.

Massachusetts

DORCHESTER—The Tide Water Oil Co., 60 Cambridge St., Allston, Mass., will commence the immediate construction of a new storage and distributing plant on Dorchester Ave. near Locust St., Dorchester, comprising a 1- and 2-story building, with about 15,000 sq.ft. of area, estimated to cost close to $75,000.

Missouri

ST. LOUIS—The Ho-Ro-Co Mfg. Co., 110 Locust St., manufacturer of flavoring extracts, etc., has plans nearing completion for the construction of a 3-story and basement plant, 60x100 ft., at Leffingwell and Dodier Sts., to cost about $55,000. Edward Lantz, 603 Post-Dispatch Bldg., is architect. N. G. Roth is president.

ST. JOSEPH—Morris & Co., Union Stockyards, Chicago, has plans in progress for the construction of a 4-story and basement lard-refining plant at St. Joseph, to replace the factory recently destroyed by fire, with loss estimated at approximately $100,000, with machinery. The new plant, it is said, will cost in excess of this amount.

Nevada

ELY—The Nevada Consolidated Copper Co. will equip its new concentrating plant, to be constructed to replace the McGill concentrator recently destroyed by fire, for a capacity of about 4,000 tons of ore per day. The unit will form sections Nos. 3 and 4 at the main works. It is estimated to cost close to $1,000,000, with machinery.

New Jersey

MORRISTOWN—The Morristown Electric Steel Foundry, Inc., 106 Water St., recently organized with a capital of $125,000, has acquired the former plant of the Liberty Steel Co. in the Shelley Terminal district, for the establishment of a new works for the manufacture of steel castings by an electrical process. Immediate possession will be taken, and it is planned to commence production at an early date. The company is headed by J. Lovell Paulmier, Samuel B. Illingsworth and Richard B. Eurich.

TRENTON—A committee of trustees of the Empire Tire & Rubber Corp., East Clinton Ave. and Mulberry St., manufacturer of tires and mechanical rubber goods, now in receivership, is perfecting plans for a reorganization of the company. The property will be offered for sale on Sept. 13. The new organization will be headed by W. T. Baird, A. W. Pickford and former Governor E. C. Stokes.

NEWARK—The Pittsburgh Plate Glass Co., 290 Elizabeth Ave., will break ground at once for the construction of a new 1-story plant, 66x110 ft., at the foot of Chester Ave. at the Passaic River, to be equipped for the manufacture of linseed oil products. It will cost about $160,000. The company will also construct a 4-story elevator, 46x46 ft., to be used for the storage of raw material, estimated to cost about $40,000. The buildings will be used in connection with the paint division of the company.

New York

LONG ISLAND CITY—The Mathieson Alkali Works, 25 West 43rd St., New York, has leased a building on 14th St. near Van Alst Ave., Long Island City, from the Connelly Iron Sponge & Governor Co., and will equip the structure for a new experimental works.

NEW YORK — The Mesabi Iron Co., 25 Broad St., operating magnetite ore properties in Minnesota for the manufacture of iron ore concentrate, or sinter, has plans under way for extensions in the plant to handle about 30,000 tons of material per day for a finished production of approximately 10,000 tons daily. It is purposed to install new machinery at the crushing plant and other departments to more than treble the present capacity. To provide for the expansion the company is disposing of a stock issue of $600,000. D. C. Jackling is president, and W. G. Swart, vice-president and general manager.

BROOKLYN—The Norman Bronze Co., 100-12 Provost St., has filed plans for the construction of a 1-story foundry addition.

LONG ISLAND CITY—Joseph R. Greenwood is organizing a new company to operate an enameling works. The building at 66 Myrtle Ave. has been leased from the Commercial Research Corp. for the proposed plant, providing about 25,000 sq.ft. of floor space. Immediate possession will be taken, and equipment installed.

YONKERS—The Arlington Chemical Co., 100 Hamilton St., has awarded a contract to the Turner Construction Co., 244 Madison Ave., New York, for the construction of a new 4-story plant, 60x200 ft., with laboratory, to be located on Harriett St. Work will be commenced at once.

North Carolina

HIGH POINT—The Marietta Paint & Color Co., Marietta, O., has plans under way for the construction of a new 4-story plant at High Point, for the manufacture of a general line of paints and colors. It is planned to commence construction at an early date.

Ohio

AKRON—The International Lead Refining Co., East Chicago, Ind., a subsidiary of Anaconda Copper Mining Co., New York, has commenced the clearing of the site on East Talmadge Ave., North Akron, recently acquired, for the construction of its proposed new plant, for the manufacture of zinc oxide. The units to be constructed at the present time will cost about $500,000, with machinery. It is planned to build other units at a later date. E. T. Gillen, 212 Ohio Bldg., Akron, is engineer. The company is said to be planning for the construction of a new 1-story addition to its zinc oxide works at East Chicago, 50x100 ft., estimated to cost approximately $50,000, with machinery installation.

Pennsylvania

SPRING GROVE—The P. H. Glatfelter Co. will commence the immediate installation of new machinery and equipment at its local paper mill. The plant will be considerably enlarged for increased capacity.

CONSHOHOCKEN—A new 1-story foundry will be constructed at the plant of the Montgomery Foundry & Fittings Co., to be equipped for a daily production of approximately 100 tons of gray iron castings.

PITTSBURGH—The Stroh Steel-Hardening Process Co., Westinghouse Bldg., has plans nearing completion for the construction of a new addition to its steel foundry at Ridge Ave. and Chateau St., to cost about $250,000, with equipment. Work on clearing the site is under way. W. Y. Stroh is president.

Tennessee

MEMPHIS—The Indiana Board & Filler Co., Vincennes, Ind., lately organized with a capital of $750,000, has acquired the local plant of the Tennessee Fibre Co., located in the North Memphis district. The new owner will take immediate possession of the plant for the manufacture of strawboard and fiber products, with department for a complete chemical treatment of straw materials used. The present works will be enlarged and considerable new machinery installed.

Texas

FORT WORTH—The Armstrong Steel Co., recently organized with a capital of $2,500,000, to take over and operate the iron and steel plant of the George W. Armstrong Co., has plans in progress for remodeling and improving the local works, converting the plant from a present line of general iron products to the manufacture of steel specialties. New mills will be constructed and considerable machinery installed, estimated to cost approximatey $1,000,000. The company is disposing of a stock issue to provide for the expansion. George W. Armstrong is chairman of the board; R. L. Van Zandt, president; and David R. Knapp, consulting engineer, formerly connected with the Eastern Steel Co., Philadelphia, vice-president in charge of operations.

YOAKUM—In connection with the proposed expansion at the plant of the Texas Hide & Leather Co., a 1-story tanning plant will be built, 30x150 ft. Two other buildings will be erected, 50x100 ft. and 50x80 ft. respectively. J. B. Harris is general manager.

Virginia

LEXINGTON—The Board of Directors of the Washington & Lee University will install a complete chemical laboratory in a new 3-story building at the institution, for which plans are being prepared. The structure will cost about $150,000. Flournoy & Flournoy, 306 St. Paul St., Baltimore, Md., are architects.

New Companies

THE CHAPMAN PRODUCTS CO., Centerdale, North Providence, R. I., has been incorporated with a capital of $25,000, to manufacture chemical products, germicides, etc. The incorporators are M. L. Merithew, R. S. Thornton and E. B. Chapman, 131 Greenville Ave., Manton, R. I.

THE REICH-ASH CORP., New York, N. Y., care of N. D. Le'man, 291 Broadway, representative, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are S. and L. R. Reich, and S. Ash.

THE NEW JERSEY BRICK CO., INC., Eatontown, N. J., has been incorporated with a capital of $20,000, to manufacture brick and other burned clay products. The incorporators are Eugene A. H. Watson, Walter T. Spalding and Theobald Mincer, all of Eatontown. The last noted represents the organization.

THE BURKE-GREIS OIL CO., Tulsa, Okla., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are John F. Burke, D. deLace Greis and Henry N. Greis, Tulsa. The last noted represents the company.

THE COLUMBIA LEATHER GOODS CORP., New London, Conn., has been incorporated with a capital of $500,000, to operate a tannery and manufacture leather goods. The incorporators are Inez C. Delgado, Samuel Friedman and M. P. Breen, 54 West 90th St., New York, N. Y.

THE FRAHER BRASS WORKS, INC., 14 South Jefferson St., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture brass, bronze and kindred metal products. The incorporators are L. L. Richmond, Lowell A. Lawson and Thomas T. Dudley, Jr.

THE CAROLINAS CHEMICAL CO., Columbia, S. C., has been incorporated with a capital of $100,000, to manufacture chemicals, fertilizers and kindred products. The incorporators are Iredell Jones, Jr., and W. D. Black, Columbia.

THE VENEZUELA OIL CORP., Boston, Mass., has been incorporated with a capital of $300,000, to manufacture petroleum products. Raymond D. Smith, 55 Congress St., Boston, is president and treasurer.

THE MASTER CHEMICAL CO., Rochester, N. Y., care of J. E. Whitley, attorney, Rochester, representative, has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are L. and P. S. Burnherr, and S. R. Joffe.

THE SEWICKLEY SOAP WORKS, INC., Sewickley, Pa., has been incorporated under Delaware laws, with a capital of $50,000, to manufacture soaps and kindred products. The incorporators are Norman B. Abercombe, Paul and R. C. Wright, Sewickley. The last noted represents the company.

THE BENSON-THARPE PAINT CO., Birmingham, Ala., has been incorporated with a capital of $50,000, to manufacture paints, varnishes, etc. Y. K. Benson is president; and W. A. Tharpe, vice-president, both of Birmingham.

THE INTERSTATE CHEMICAL CO., Providence, R. I., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are Philip C. Joslin, R. A. McDonald and Thurston Seabury, Cranston, R. I. The last noted represents the company.

THE RELIABLE GAS & OILS, INC., Newark, N. J., has been incorporated with a capital of $50,000, to manufacture lubricating oils, etc. The incorporators are Harry B. O'Connell, and William F. Haas, 1212 Broad st., Newark.

THE FOURLOCK TILE CORP., American Bldg., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture concrete tile blocks and kindred products. The incorporators are Harry W. Somers, William L. Breman and Frank E. Holt.

THE PHOSPHOGEN FERTILIZER CORP., Richmond, Va., has been incorporated with a capital of $10,000,000, to manufacture commercial fertilizer products. Horace S. Wright is president, and N. T. Cook, secretary, both of Richmond, Va.

ARTHUR J. CAHILL & CO., 96 Linden Ave., Jersey City, N. J., has filed notice of organization, to manufacture chemicals and chemical byproducts, dyes, etc. Arthur J. Cahill heads the company.

THE CHARLES BECK CO., Philadelphia, Pa., care of Archibald T. Johnson, 1617 Land Title Bldg., representative, is being organized to manufacture paper products. The company is headed by H. P. and L. Beck and Andrew Simon. Application has been made for a state charter.

THE INDUSTRIAL PRODUCERS' & REFINERS' CORP., Wilmington, Del., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, has been incorporated under state laws, with a capital of $12,000,000, to manufacture petroleum products.

MAXUDIN & CO., INC., New York, N. Y., care of Niles & Johnson, 54 Wall St., representatives, has been incorporated with a capital of $100,000, to manufacture oil products. The incorporators are W. R. Fuller, R. Q. Kelley and F. H. Medbury.

THE NEW YORK VITREOUS ENAMEL PRODUCTS CO., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., representative, has been incorporated under Delaware laws, with a capital of $300,000, to manufacture vitreous enamel ware and kindred burned clay products.

THE SEABOARD BRASS & COPPER CO., 805 Continental Bldg., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture brass, bronze, copper and kindred products. The incorporators are Harvey H. Wilson, Edwin M. Talbot and Herbert Langrall.

THE AMERICAN GLASS EXPERIMENTAL WORKS, 104 Point St., Providence, R. I., has filed notice of organization to manufacture glass specialties. William Cepek heads the company.

THE P. M. REFINING CO., New York, N. Y., care of I. H. Bookman, 799 Broadway, representative, has been incorporated with a capital of $10,000, to operate a metal refining plant. The incorporators are A. S. Bockman and E. H. Vogel.

THE INTERSTATE OXYGEN CO., Wheeling, W. Va., has been organized under state laws to manufacture commercial oxygen products. The incorporators are H. G. Beckett, F. C. Niebergall and G. H. Helfer, all of Wheeling.

THE BRIDGEPORT BRONZE CO., Bridgeport, Conn., has been incorporated with a capital of $200,000, to manufacture bronze, brass and other kindred metal products. The incorporators are H. M. Trainor, H. L. Shaff and Jonathan Grout, 886 Main St., Bridgeport.

THE STRAW CELLULOSE PRODUCTS CO., Portland, Me., has been incorporated with a capital of $1,000,000, to manufacture paper and pulp products under a special process. Charles M. Drummond is president; R. B. Buzzell, treasurer; and Wadleigh B. Drummond, clerk, all of Portland. The last noted represents the company.

THE INDIANA OIL & SULPHUR CO., Mooresville, Ind., has been incorporated with a capital of $500,000, to manufacture oil and sulphur products and affiliated specialties. The incorporators are M. H. and Alfred L. Thomas, and Pharoah H. Hill, all of Mooresville.

THE SOMERTON FOUNDRIES CORP., Philadelphia, Pa., care of the Capital Trust Co. of Delaware, Dover, Del., representative, has been incorporated under Delaware laws with capital of $250,000, to manufacture iron, steel and other metal castings. The incorporators are M. F. Devine and S. R. Kerr, Philadelphia; and C. L. Hadgkiss, Camden, N. J.

THE WESTERN OIL & REFINING CO., 1828 Second Ave., Rock Island, Ill., has been incorporated with a capital of $25,000, to manufacture refined oil products. The incorporators are James McCrory, Carl J. Mueller and Patrick L. Welsh.

THE HARLEM CORK CO., New York, N. Y., care of L. A. Cuvillier, 154 East 121st St., representative, has been incorporated with a capital of $5,000, to manufacture cork products. The incorporators are S. Becker, A. H. and C. F. Stahl.

THE SMITH-WILKINSON GUANO CO., Spartanburg, S. C., has been incorporated with a capital of $25,000, to manufacture fertilizer products. The incorporators are Floyd T. Smith and J. C. Wilkinson, both of Spartanburg.

THE GOBLE RUBBER PRODUCTS CO., Cleveland, O., care of Homer J. Smith, Wyoming, Del., representative, has been incorporated under Delaware laws, with a capital of $50,000, to manufacture rubber specialties. The incorporators are H. L. Indal Smith, M. L. Merchant and J. M. Whitford, all of Cleveland.

THE PENNSYLVANIA PRODUCTS LABORATORIES, INC., Brooklyn, N. Y., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical by products. The company is represented by F. G. Milligan, 375 Fulton St., Brooklyn. The incorporators are C. Jacob, B. Miller and A. Devine.

THE MEXIA-FREESTONE OIL CORP., Mexia, Tex., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated with a capital of $5,000,000, under state laws, to manufacture petroleum products.

SCHWARTZ BROTHERS, INC., 309 East Center St., Baltimore, Md., has been incorporated with a capital of $25,000, to manufacture lubricating oils. The incorporators are Max L. and Louis A. Schwartz.

THE BAFFETTI VULCANIZER SYSTEM, INC., 917 West Washington Boulevard, Chicago, Ill., has been incorporated under state laws, to manufacture rubber specialties, rubber reclaiming fluids, etc. The incorporators are Louis A. Baffetti and Frank Fox.

THE LAKE SHORE OIL CO., 1125 West 79th St., Chicago, Ill., has been incorporated with a capital of $20,000, to manufacture refined oil products. The incorporators are George W. and Frank B. Busch, and Walter A. Johnston.

THE GRAPHO CRAYONS CO., St. Louis, Mo., has been incorporated with a capital of $50,000, to manufacture crayons, chalks and kindred products. The incorporators are W. L. Deist and R. H. Taylor, both of St. Louis.

THE AMERICAN CARBON ELIMINATOR CO., Brooklyn, N. Y., care of W. L. Morehouse, 50 Court St., representative, has been incorporated with a capital of $20,000, to manufacture special compounds for carbon elimination. The incorporators are N. Friedman and M. M. Rutchik.

THE BEAVER PETROLEUM CO., Buffalo, N. Y., care of Robert C. Palmer, Ellicott Square, representative, has been incorporated with a capital of $500,000, to manufacture petroleum products. The incorporators are F. L. Danforth, B. Rumsey and W. S. Jackson.

THE GLOBE STEEL TUBE CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws, with a capital of $10,500,000, to manufacture steel tubing and affiliated products.

THE PEERLESS OIL CO., Richmond, Va., has been incorporated with a capital of $500,000, to manufacture refined oil products. E. E. Pratt, Paola, Kan., is president; and Guy B. Hazelgrove, Richmond, secretary.

THE AMERICAN MICA MFG. CO., Wilmington, Del., has been incorporated with a capital of $100,000, to manufacture mica products. The incorporators are Charles S. Greelman, Waynesville, N. C.; Charles E. and Frank E. Slocumb, both of Wilmington. The last noted represents the company.

THE NYPROS STEEL CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., has been incorporated under Delaware laws with a capital of $5,250,000, to manufacture steel products.

Coming Meetings and Events

ALPHA CHI SIGMA dinner, during the Chemical Exposition, will be held Thursday Sept. 14, at 6:30 p.m. at Keen's Chop House, 107 West 44th St., New York City. Members are requested to register at *Chem. & Met.'s* booth at the Exposition.

AMERICAN CHEMICAL SOCIETY is holding its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition at Atlantic City, Oct. 23 to 28.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its 126th meeting at San Francisco, Calif., Sept. 25-29, 1922.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS will hold its sixteenth annual convention Sept. 11 to 15 at Cleveland Public Hall, Cleveland, Ohio.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York, Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer, but will resume them in October.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a 3-day national convention in New York, beginning Oct. 18. The general topic of the convention is "Economics of Industry."

onferees Report On the Tariff

ANOTHER turn was given to the kaleidoscope of tariff legislation last week when the conferees greed upon the dye embargo and revised the ad alorem and specific duties on intermediates and dyes. n the face of it this is favorable to the chemical ndustry and gives a new lease of life to the embargo. is questionable, however, whether the action will be pproved by either the House or the Senate. The only ertainty is that the change will precipitate a fight in oth houses.

It will be recalled that the Fordney bill eliminated ne embargo altogether; that the Senate Committee on inance restored it, but that the Senate finally rejected after a spirited debate. The only way in which the nferees could revive the issue was by eliminating the ction in the Senate bill which authorized its repeal. here is a question whether this is permissible under nference rules, so that a fight will be waged not only n the embargo itself but also on the validity of the nference agreement. Meantime the Bursum amendent, carrying high ad valorem and specific duties, as been rejected, and it is impossible to foresee at his writing how the dye industry will come out of ne mêlée.

overnment Files Suit Against Chemical Foundation

CHARGING conspiracy to create a dye and chemical monopoly in the United States, with the Chemical oundation as a device for acquiring German patents, ne Attorney-General on Sept. 8 filed a suit in quity in the United States District Court at Wilmingon, Del., against the Chemical Foundation, Inc., emanding a return to the Alien Property Custodian of ll German patents and other rights held by this oranization. An analysis of the complaint, which covers nore than 500 printed pages, including exhibits of sevral hundred pages, reveals the line of attack on which he government will proceed. In the first place, it is lleged that the price paid for the patents by the hemical Foundation was grossly inadequate, so much o that if the sale is sustained it would constitute conscation and a violation of trust. Next, the government ttacks the authority under which the sale was made nd the validity of an executive order by President VILSON attempting to validate certain acts of the then ssistant Secretary of State. It is claimed that both f these officials were unaware of the facts in the case vhen taking their actions and that the Chemical oundation through its representatives "put something ver" on the government.

The conspiracy phase of the government's suit is a nost interesting one, because it brings into the controversy not only some leading chemical manufacturers but also certain trade associations and technical societies, naming them all as conspirators in the creation of the Chemical Foundation, which was to pull German chestnuts out of the fire for American chemical industry. No less interesting is the charge that these conspirators hoodwinked the government by misrepresentation or only partial representation of the facts. This is the government's side of the story, and it is evident that it calls for considerable light which the Chemical Foundation's answer undoubtedly will shed on the whole matter.

Public Appreciation of Chemical Warfare Service

EDUCATION of the public takes time. This is strikingly illustrated in the attitude of the people generally toward the Chemical Warfare Service, regarding which a large amount of information has been printed in the last 4 years. In 1918 the American public had no other idea than that the use of gas in warfare was barbarous in the extreme, with no redeeming feature. To dislodge that conception from the minds of 110,000,000 people has been a task of unusual difficulty, but General AMOS A. FRIES, Chief of the Chemical Warfare Service, believes that a majority of the people at last have been brought to estimate the value of the service more accurately.

Information reaching the Chemical Warfare Service directly and the opinion of Senators, Representatives and other officials who are in close touch with the people all lead to that conclusion. It is believed that this feeling will be strengthened as the public learns that the peace-time activities of the service carry with them great possibilities in the public interest. For instance, the Chemical Warfare Service, with the aid of representatives of the Public Health Service and of the Navy, has developed a substitute for hydrocyanic acid gas which removes all danger of accidental death from the use of that gas as a fumigant. The substitute is cyanogen chloride, which is a powerful tear gas when used in concentrations of only one-eighth the amount necessary to cause death. As soon as sufficient supplies of the new gas are available, it will be used exclusively by the government in the fumigation of ships.

Encouraged by the success of the experiment with cyanogen chloride, the chemists at Edgewood Arsenal are now getting encouraging results from experiments in mixing a sneezing gas with illuminating gas so that sleeping persons will be awakened in case unburned illuminating gas should escape in the room. The property of the gas which causes sneezing is destroyed when the gas is burned. Progress continues to be made in the use of poison gas against insect and rodent pests, notable work having been done recently in combating

locusts in the Philippines. Work is also continuing in the hope of finding a successful way of using gas in the eradication of the cotton boll weevil. All of which leads to the confident belief that gas will be found to be the most effective weapon that can be employed in the fight on insect and rodent pests. Thus are the means of war converted to the uses of peace; and meantime the knowledge gained will be a comforting asset in time of emergency.

The Universal Curse—Work

THE basis of the philosophy both of the men who exercise creative intelligence and of the great mass of the workmen, both skilled and unskilled, is the same: "Work is a curse." The practice growing out of the philosophy is different. The investigators and inventors are endeavoring to lessen the amount of work that has to be done to compass a given quantity of production, by improving methods, by finding short cuts. The workman is endeavoring simply to reduce the amount of work he must do individually without reducing the compensation received.

This is not a case of different reactions to environment, for the environments are different. One cannot assert that if men were to change places the reactions in the environments would be changed.

We appear to be, on the whole, sadly lacking in the application of psychology. There is much criticism of workmen for wanting to do less work and for wanting to get more pay for what they do. Great economic truths are hurled at them, with no results measurable by instruments of the present standard of sensitiveness. We poke fun at the remaining men who believe that breaking windows is good for business because it makes work for the glazier. Only the densely ignorant can have such a viewpoint, we opine. Yet we have a group of men, elected by men and women who must have thought the candidates possessed some intelligence, who have passed a tariff act plainly based on the philosophy that we want only so much work to be done, and that if we permit foreigners to do any of it we shall have so much less to do ourselves.

The captains of industry, the *entrepreneurs*, the employers—to name more specifically a class—should not expect employees and workmen to have a different philosophy than they themselves have. They all believe that work is something to be avoided, provided the results or rewards are still obtained, and that belief cannot be eliminated as a basis of conduct. It is a fact that must be recognized.

The burden of improvement rests not upon artisans or unskilled workmen, but upon those who invent and devise. Hitherto the activities of the men of creative intelligence have been directed chiefly to reduction in the total quantity of work to be done to achieve given results. They would like, to give an illustration, to replace a gang of four men by a gang of three men, each of the three men working as hard as each of the four men had to work. There is another field, little considered, that of making the work of the four men less irksome, whereby these four men become more contented than are four other men who are working the old way and who become ambitious for promotion to the less irksome work.

The general principle involved, that work should be made less irksome, is universally recognized. The most obvious proof of this recognition is the large part played in "welfare work" by the providing of [illegible]. Undoubtedly all such efforts, if intelligently directe are good, but it is plain that they represent an ope confession by the employer that the work of the em ployee is irksome. They improve conditions, no doub but at the same time they emphasize in the mind of th workman the point that improvement is confessed desirable. No competition among workmen is produce the benefits of welfare work being open to all. Whe however, some jobs are made less irksome than othe jobs, competition to possess the better jobs is stim ulated.

A Survey Of Business

"THEY are shipping niggers (*sic*) from Birmin ham by the trainload."

"California is prosperous. People must eat, and th West can always feed them."

In addition, there were a number of men who thanke whatever gods there are that they still hold their pos tions. All these, and many more, are the concomita joys of an editorial survey of general business cond tions that we have recently completed. We aske whether business was good, fair or poor. We aske whether unemployment was increasing or decreasin and we further inquired whether the addressee was em ployed. We addressed our inquiry to technical me distributed all over the country. Some of them a not technically trained, but all of them have a technic background. They are engaged largely in manufactu ing, and the products are in general connected wit chemical or metallurgical industries.

A gratifyingly small number of men reported tha they were unemployed. It is reasonable to assume tha a relatively large percentage of unemployed men woul answer a questionnaire of this kind, and it is probabl safe, therefore, to assume that 4 per cent is a hig figure for unemployment among technical men.

All sections reported unemployment decreasing. Th West was apparently surer of it than the East, for ove 75 per cent of the men from the Middle and Far Wes reported unemployment on the decrease. In the East 66 per cent believed that more men are at work now.

The accompanying table represents the opinions re ceived on business conditions. The similarity of th replies from the different sections of the country i striking, and a healthy note of optimism is apparen That business should be reported good in over 30 pe cent of the total replies is certainly encouraging. A slightly higher optimism, whether of temperament o of fact, is to be noted in the Middle and Far West, bu the similarity is rather more striking than the sligh difference.

Business Is	East, Per Cent	Middle West, Per Cent	Far West, Per Cent
Good.....	25	32	30
Fair.....	65	62	58
Poor.....	10	6	12

Those industries which were reported as "enjoying poor business were made a subject of special study It is quite reassuring, because no one industry wa mentioned frequently. Individual companies seem t have a continuation of lean years in dyewood extracts dyestuffs, copper, zinc, beet sugar, machinery, soap brass, etc. The striking thing, however, is not tha individual companies are having hard times but tha hard times are not general and that they are not con fined to any particular industry.

It is somewhat unwise to overemphasize the value o

ind yet the men have intimate contact with their indus-ries. Many of them are production heads, and all of hem are engaged in production work. It is perhaps air, then, to assume that the opinions have more weight han a casual opinion ordinarily would. The indication s that, disregarding enforced idleness through strikes, he country is on the road to business health.

Building With Foresight

RATIONAL, scientific plant design and layout are more often notable for their complete absence from the chemical plant than for their presence. This has been largely brought about by the circumstances under which chemical industry has developed—circumstances which preclude the use of any effective prevision.

Some of the points made by contributors to *Chem. & Met.'s* recent Exposition issue bring this situation clearly before the reader; and we feel that the course of conduct which would follow a complete realization of the present situation and the remedies for it is one that can be profitably considered by all those who can help to put it into effect.

Among other contributors, FRANK D. CHASE, in referring to this lack of forethought, said:

"The result has been in most plants a hodge-podge of buildings built one at a time without reference to co-ordination of manufacturing operations; without thought for future growth, either as a whole or for single units or departments; and without thought, in very many instances, of the physical comfort and welfare of employees."

A. E. MARSHALL, in his contribution on the design of chemical plants, expressed the need of this foresight in the following words: "In considering the design of a new plant, the chemical engineer has several important factors to take into account. One which has received least attention in the past and which has caused later on in the life of chemical plants either unnecessary cost of product or prevented possible reduction is the lack of provision for future expansion."

It seems axiomatic that each owner of a chemical plant desires his business to grow. A static condition is but little better than a reduction of business and a healthy growth is one of the requisites of real success. If the product which is manufactured is worthy and well marketed, the plant will inevitably be faced with a demand for increased output.

If the original plant was not built with this end in view, there seem to be only two ways open to meet this situation. Either a complete new plant can be built or additions can be crowded into the existing plant wherever an available corner can be found. Neither of these expedients has the effect of lowering the costs in the degree that could reasonably be expected to follow increased output.

How much better, then, to provide for a reasonable expansion at the time the plant is built. If this is done, capacity can be added as the need for the increase occurs. Such an expansion invariably results in more output per unit of labor; and there are certain features of the plant which will not have to be duplicated, but can serve the increased capacity as well as they did the original. The result of this is the reduced production cost that should always follow increased output.

One of the greatest of engineering firms has adopted as its slogan the words: "BUILDING WITH FORESIGHT." It may have the use of this phrase copyrighted for advertising purposes, but its application to industry is open to all. Let chemical industry adopt this as its watchword and by the use of an intelligent prevision escape the recurrence of the mistakes of the past.

Opportunities in The Leather Industry

AS MODERN chemical science has developed, workers in the different industrial fields have been quick to apply promising concepts to their own problems in the hope of obtaining a clearer understanding of the processes involved. Where it has been possible to determine the fundamentals, progress has been invariably rapid and often phenomenal. In some industries the required information became available at a fairly early period in the growth of the science, while others find even present knowledge inadequate.

Typical of this latter group is the manufacture of leather, which is still largely an art. Through practical experience, supplemented by knowledge which has accumulated as a result of centuries of experimentation by methods of elimination or trial and error, the tanner is able to manipulate successfully and profitably complex reactions, the mechanism of which still baffles the chemist. Progress in an art is often due to the application of methods quite similar in principle to those by which a science advances. Indeed, the progressive tanner has really employed scientific methods in attempting to trace cause and effect in the maze of variables confronting him, so that in this sense there may be said to be a science of leather manufacture.

Of necessity, development in this empirical way has been slow, and real progress will not result until the fundamentals have been established. At present, in spite of the excellent pioneer work which has been done, even a chemist whose training has included the latest developments of physical chemistry, the chemistry of proteins, tannins, colloids and of bacterial and enzyme action, will find difficulty in studying many of the reactions which take place. Attempts at process improvement by chemists with inadequate training have so often resulted in disaster that many tannery chemists find their efforts confined to laboratory control methods, where again the lack of fundamental data forces them to adopt empirical makeshifts. While control methods are necessary, there is so much work of more vital importance to be done that it would seem that there is a decided tendency among American leather chemists to place undue emphasis on analytical methods.

Fundamental work of the character discussed has been started within the last few years, but many of the results will require intelligent interpretation and application to plant conditions before the tanner will benefit. Herein lies an opportunity for chemists equipped with the thorough modern training which will enable them to qualify. As the industry is not sufficiently aware of its own needs to seek such men, they will be compelled to take the initiative. No small part of their task will be to convince the tanner that chemistry has something more to offer than analytical methods—that it can co-operate intelligently in the improvement of processes—but once this is accomplished both the industry and the status of the chemist within the industry will benefit. For the chemist will not receive proper recognition in the leather industry until he is able to stand shoulder to shoulder with the tanner in the development of the manufacturing processes to their highest efficiency. The field is open and the rewards are certain for those who have the ability and the determination to make good.

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

LONDON, Aug. 21, 1922.

THERE is little to report in regard to chemical markets, which are just recovering from the usual effects of the holiday season, but on the whole demand continues to improve and the outlook is promising. The export trade has been adversely affected by the collapse of the German exchange and a further depreciation is expected. This, it is thought, may have a beneficial effect upon exports to non-European countries. Although the price tendency is upward, the standard prices for soda products have recently been reduced, while the increase in price fixed for the current season by the Sulphate of Ammonia Association has been less than was expected under present circumstances. Coal-tar products are an uncertain market, but pitch is very firm and makers are holding back supplies. Arsenic compounds and particularly zinc oxide have been in good demand, depleted stocks and a rise in the price of spelter being mainly responsible in the latter case. The new trade index, "Where to Buy"—Everything Chemical, referred to in my notes for May, has now been published and was favorably received by the trade. This and other publications are symptomatic of a distinct tendency for better organization and effective propaganda in the chemical trade.

A Novel Design for Non-Rigid Filter Presses

Gavin A. Renton has worked out the details of a non-rigid type of chamber which enables the cake between the plates to be subjected to additional pressure by squeezing the whole press together after the completion of the normal filtering operation, like a concertina. Metal hoops forming a nearly complete circle in section and surrounding a rubber core are used as distance pieces between the filter press plates. Using vanadium spring steel with a high elastic limit, the relation between the dimensions and thickness of these hoops has been carefully worked out in order to give correct results. In a given case the normal thickness of the cake can be reduced from $1\frac{1}{4}$ in. to $\frac{3}{4}$ in., using metal filter cloth, and in certain cases a non-rigid press of this type should have distinct possibilities.

Yet Another Process for Cheap Hydrogen Manufacture

The synthetic ammonia industry is mainly responsible for the development of commercial methods of hydrogen manufacture, the two main sources being coal and water. Electrolytic hydrogen is dependent upon very cheap water power, and water gas made from coke has been the main source of hydrogen in this and other countries with adequate coal supplies. Claude has proposed to remove the hydrogen from coke-oven gas by fractional liquefaction, but in making coke-oven gas only about one-quarter of the hydrogen is liberated, whereas many coals contain about 5 per cent by weight of hydrogen, equivalent to about 20,000 cu.ft. per ton. Jaques & West are now developing a new process which is likely to give the maximum possible yield of hydrogen per ton of coal, this being attained by combining in a single apparatus the distillation of coal, the formation of water gas from the resulting coke and the conversion of all carbon monoxide into carbon dioxide and hydrogen by reaction with steam in the presence of a catalyst. The carbon dioxide is removed by absorption in water under pressure. An experimental plant, consisting of a modified form of Tully complete gasification plant, is now in operation in the north of England, the hydrogen present in the coal being very completely liberated by passing the crude coal gas through the hot zone in the producer, so that the tar, oils, methane and other hydrocarbons are "cracked" or split up into hydrogen and carbon, the carbon reacting with steam to form water gas. The catalyst used is stated to be cheap and reliable and a yield of about 45,000 cu.ft. of hydrogen per ton is stated to have been obtained at a cost of rather more than 1 shilling per thousand cubic feet. It is suggested that the mixture of hydrogen and nitrogen in the proportions required for synthetic ammonia manufacture may be obtained by adding a measured quantity of air to the hydrogen and passing the mixture over a catalyst so that combustion takes place quietly.

Stainless Steel for Chemical Plant

Independent investigations in this direction have been proceeding for some months, but Thomas Firth & Sons, Ltd., of Sheffield, has rendered a service by publishing a textbook on data from investigations carried out in its research laboratories. This book can be recommended for study by all who have the development of chemical plant at heart, and it is particularly interesting to notice occasional differences in the properties claimed for Firth's products as compared, for instance, with Krupp's V2A steel. The most striking of these is perhaps the non-magnetic properties of V2A and the claim that it can be autogenously as well as electrically welded. The most outstanding features are the complete resistance of the new material to caustic alkali, ammonia, copper sulphate and nitric acid of various strengths, its use for optical purposes and its capacity for withstanding high temperatures without excessive loss of strength. Curiously enough, acetic, citric, lactic and tannic acids will attack stainless steel, but natural products such as vinegar, lemon juice, sour milk and tanning extracts, although containing these acids, are without action. The material should be increasingly used in the chemical and other industries, particularly if further researches are generally published and if it should be possible to spray or deposit the metal. The question of price is of considerable importance and at present seems to be in the neighborhood of one dollar per pound. Firth & Sons and also other firms have, however, been developing another variety, which may be termed stainless iron and described as an iron-chromium alloy with a carbon content of under 0.1 per cent. It should be possible to market this and similar soft metals at about half the above price.

General Notes

In my contribution for March of this year I referred to the controversy regarding the presence of carbon monoxide in coal gas and meanwhile Prof. H. E. Armstrong has been investigating the carbon monoxide content in tobacco smoke. Experiments made at the South Metropolitan Gas Co. showed that cigar smoke contained 5 per cent and upward of carbon monoxide, while pipe and cigarette smoke averaged about 1 per cent. Rapid smoking considerably increased the carbonic oxide content.

Max Muspratt is the new chairman of the Association of British Chemical Manufacturers, succeeding Sir John Brunner.

The Artificial Silk Industry

A Concise Review of the Development of the Various Processes, With a Discussion of Their Relative Merits and a Summary of Patent Literature

By Hugo Schlatter

FROM time immemorial man has made use of a variety of animal and vegetable fibers for covering and adorning his body. By careful spinning, bleaching, dyeing, artful weaving and knitting, he has tried to improve and better adapt them to his uses; but it has been only in recent years that he has attempted and succeeded in imitating any of them. It is natural that these efforts of imitation should have been concentrated on silk, the most beautiful and costly textile material.

Natural silk is the product of the silk moth, *Bombyx mori*, and a few other insects closely allied to it. Its cultivation is an ancient industry in China and has spread from there to other countries, particularly Japan, Asia Minor and the southern countries of Europe, where the climate is favorable to the growth of the mulberry tree, whose leaves nourish the worms. In spite of a suitable climate in parts of the United States and repeated efforts aided by the government, the cultivation of the silkworm has never been a success in this country, as it depends on a plentiful supply of cheap labor. Chemically, silk fiber consists of a core of fibroin ($C_{15}H_{23}N_5O_6$), which constitutes 75 to 82 per cent of the entire mass, a covering of sericin or silk albumen ($C_{15}H_{25}N_5O_8$) and a little waxy and coloring matter. Fibroin is soluble in strong alkalis, concentrated sulphuric and nitric acids, concentrated zinc chloride solutions, ammoniacal solutions of copper oxide and nickel oxide. Its solubility in ammoniacal nickel oxide distinguishes it from cotton and artificial silk. Sericin is soluble in hot water and warm soap solutions. Silk is quite hygroscopic, containing under normal atmospheric conditions about 11 per cent of moisture.

Artificial silk is chemically quite different from the natural product. It is a derivative of cellulose and resembles silk only in certain physical characteristics, particularly the luster. At the most, it contains only traces of nitrogen.

At the present time there are four types of artificial silk manufactured commercially: Nitrocellulose silk (Chardonnet, Lehner or Tubize silk). Cuprammonia silk (Despaissis or Pauly silk, Glanzstoff). Viscose silk. Cellulose acetate silk. The first three are hydrated forms of cellulose, whereas the last named is, as its name implies, an ester of cellulose.

History of Artificial Silk

The first hint as to how silk might be imitated was given by Réaumur, the French scientist, who as early as 1734 suggested the drawing of threads from the gums and resins used in the manufacture of Chinese varnish[1]. It was more than 120 years later, however, before his suggestion bore fruit, when Andemars of Lausanne obtained a patent (Br. Pat. 283; 1855), according to which he made a collodion from the bast fibers of young mulberry twigs and mixed it with a solution of one part of rubber in ten parts of ether. Into this mixture he dipped a steel point and by means of it drew out a thread which was reeled in the usual way. Two years later Hughes (Br. Pat. 67; 1857) mentioned a viscous mass consisting of glue, starch, resins, etc., which he proposed to spin like glass. Ozanam was the first to suggest spinning through fine openings (spinnerets) in imitation of the silkworm[2]. In 1883 Joseph Wilson Swan of Bromley, England, produced filaments for use in incandescent lamps by extruding a nitrocellulose solution through fine openings into 70 to 80 per cent alcohol (Br. Pat. 5,978; 1883) and denitrating them by means of ammonium sulphide or other reducing agents[3]. It will be noted that Swan's method foreshadowed the essential steps of the process that first produced commercially successful artificial silk[4].

Outline of Process

In principle, the manufacture of artificial silk consists in dissolving cellulose, or one of its derivatives, in suitable solvents, and coagulating the solution, as it is extruded through fine openings, by removal or dilution of the solvent, or by decomposition of the soluble cellulose compound. This may be followed by further treatments to regenerate cellulose, as in nitrocellulose silk. The first method of coagulation is used in nitrocellulose and acetate, the second in cuprammonia and viscose silks.

The usual sources of cellulose are chemical woodpulp and cotton linters. The former is used only for the viscose process, and even there the cheapness of linters and the more uniform quality obtainable has caused manufacturers, in this country at least, to abandon woodpulp almost entirely. No matter what the source or the later process used, the first essential is a proper purification of the cellulose. It must be freed from impurities, such as grease, mineral matter, pectic substances, etc. Woodpulp in the form obtained from Norwegian spruce by the sulphide process answers these requirements sufficiently for the viscose process. Cotton linters (the short fibers remaining on the cotton seed after ginning) are boiled under a pressure of several atmospheres in a weak solution of caustic soda to which sometimes a little resin soap is added. After careful washing to remove and recover the caustic soda, the linters are lightly bleached with chloride of lime, washed again to remove all traces of chlorine and lime, and dried.

The spinning solutions must be of such character that they can be drawn out to a long fine thread which can easily be coagulated and which will have a certain elasticity and strength so that it will not break in spinning. They must necessarily be free from air, dust and other impurities that would cause uneven or defective threads. In general, the aim is to have a spinning solution that is practically on the point of precipitation

[1] "Mémoire pour servir à l'histoire des insectes," vol. 1, p. 154.

[2] *Compt. rend.*, vol. 55, p. 883 (1862).

[3] According to Lehner (*Chem. Zeit.*, p. 579, 1906) cloth made from Swan's filaments was shown at a London exhibition in 1884. A paragraph in *J. Soc. Chem. Ind.*, p. 34, 1885, mentions the product under the name of artificial silk.

[4] Similar methods, some depending on solutions of cellulose in zinc chloride, were patented in England in 1884 by Swinburne (Br. Pat. 4,121), Evans and Wynne (Br. Pat. 12,675), Watt (Br. Pat. 13,133), Wynne and Powell (Br. Pat. 16,805).

so that the thread will coagulate immediately on coming in contact with the precipitant. The viscosity is influenced by the preliminary treatment of the cellulose, the composition of the solvent and the temperature. Except in the case of nitrocellulose, the spinning liquids deteriorate on standing, especially at higher temperatures, and therefore it is usual to keep and "age" them in cold rooms that are maintained at temperatures of 4 deg. C. or lower.

The spinning apparatus consists essentially of a distributing pipe to which are attached branches carrying the individual spinnerets; a trough containing the precipitating bath into which dip the ends of the spinnerets, and a rotating receiver for the spun filaments. This receiver may be either a glass cylinder upon which the threads are wound crosswise, or a can in which the thread is deposited in skein form by centrifugal force. The spinnerets are usually made of glass connected individually to the distributing pipe, or combined in the form of a spray so that each spray furnishes the number of filaments required for one thread. The thickness of the filament is a function of the size of the spinning opening, the concentration and viscosity of the solution and the ratio of the spinning pressure to the speed with which the filament is drawn off.

Chardonnet Process

The first commercial process owes its development and practical application to the French Count Hilaire de Chardonnet, who was granted his first patent (French 165,349) in 1884. His first product was undenitrated nitrocellulose. This proved too flammable and it became necessary to remedy this defect by denitration. Chardonnet established a factory in Besançon, France, which in 1891 had a production of 100 lb. daily. By 1907 this rate had been increased to about 4,000 lb. per day. Other plants were started in Switzerland, Germany, Belgium, Hungary, Italy and England; but the last named was in existence only a short time.

Chardonnet worked with concentrated solutions of nitrocellulose (20 to 25 per cent) in a mixture of ether and alcohol which necessitated the use of relatively high pressures (40 atmospheres) and very fine spinning jets (0.08 mm.). Lehner modified this procedure by using thinner solutions (10 to 15 per cent), sometimes reducing the viscosity further by addition of acids. This made it possible for him to use much lower pressures. By drawing his filaments fine during their passage through the coagulating bath he was able to increase the size of his spinnerets still further to about 0.5 mm.

Another difference between the two methods existed in the manner of coagulation. Chardonnet's concentrated solutions made from nitrocellulose containing about 20 per cent of water harden sufficiently on exposure to moist air to be wound on bobbins without sticking and can therefore be spun "dry." Lehner spun his silk "wet"—that is, the ends of the spinnerets were immersed in water or weak alcohol, and the filaments coagulating slowly in this liquid were drawn out by winding them on cylinders at a greater speed than that with which the solution issued from the jets.

Nitrocellulose Silk

In the manufacture of the nitrocellulose itself, the properly purified cotton is dried to a moisture content of about 0.5 per cent, and nitrated at temperatures from 40 to 50 deg. C. in an acid mixture containing about 31 per cent of nitric and 54 per cent of sulphuric acid. Nitration is generally carried on in some form of mechanical dipping device[5]. After removal of the excess acid by centrifuging, the nitrocellulose is purified by boiling, pulping and washing in pure water. It is then freed from excess of water by centrifuging and sometimes further dried by displacing the water by alcohol. The solution of the nitrocellulose in the ether-alcohol mixture is carefully filtered under pressure to remove all undissolved particles and permitted to stand for several days to free it from air bubbles, which would cause weak spots or breaks in spinning. Storing the solutions in large tanks also has a blending effect and tends to make the product more uniform.

Generally sixteen to eighteen filaments are united to form one thread and given a slight twist on machines similar to those used in the twisting of natural silk in order to hold them together. From the twisting machines the threads are reeled in the form of skeins and then treated with sodium sulphhydrate to remove the nitric acid with which the cellulose had been combined. They are now washed with water, treated with hot dilute hydrochloric acid to remove iron sulphide, washed, bleached with sodium hypochlorite, washed again, sometimes passed through a soap solution to soften them, and dried.

The air from the spinning room is passed through scrubbing towers, where the alcohol is absorbed in water and the ether in sulphuric acid. The solvents are recovered from the absorption liquids, as well as from the precipitating bath, by distillation.

The advantages of the nitrocellulose process are primarily that the solution used is stable and may be kept for a long time without deterioration, and further that the mechanical processes of washing, twisting and reeling are carried on while the threads are in the thick and strong form of nitrocellulose. It has, however, many disadvantages. Nitrocellulose is highly flammable and care must be taken to keep it wet at all times. The solvents for it are expensive, volatile, flammable, and form explosive mixtures with air. Their recovery presents difficulties[6]. Expensive nitric acid is used to make nitrocellulose and must be removed without the possibility of recovering it. On denitration, the filament loses strength and weight, so in this respect it has no advantages over other forms of artificial silk.

Cuprammonia Process

The next process to find commercial application is based on the solubility of cellulose in an ammoniacal solution of copper hydroxide (Schweizer's reagent). This method is due to Louis Henri Despaissis, who was granted a patent in 1890 (French Pat. 203,741). Owing to a peculiarity of French law, the patent lapsed on the death of the inventor, which occurred a short time thereafter. In 1897 Hermann Pauly was granted German patent 98,642 (U. S. 617,009) which forms the basis of all subsequent methods. Manufacture was promptly undertaken by the Vereinigte Glanzstoffabriken A. G. in Elberfeld with factories at Oberbruch and Mulhouse, and further development is largely due to Bronnert, Fremery and Urban of this company.

The cellulose solvent may be prepared by precipitating copper hydroxide from copper sulphate solution with sodium hydroxide, washing the precipitate care-

[5] *Chem. & Met. Eng.*, vol. 26, p. 281 (1921).

[6] The alcohol consumption in the Chardonnet plant in 1907 is said to have been 4 to 5 liters per pound of artificial silk.

ully and dissolving it in aqueous ammonia. The nethod of the Glanzstoff A. G. consists, however, in the xidation of metallic copper in the presence of ammonia. A tower is filled with copper clippings and 14 per cent mmonia water. Air is blown in at the bottom of the ower, the whole system being maintained at a temperature of 0 to 5 deg. C. After about a day solution s complete and the liquid contains up to 5 per cent opper. It must be kept at a low temperature, as otherwise copper is precipitated. Purified cotton is dissolved n this solution. The spinning liquid contains 7 to 8 er cent cellulose, 2.5 to 3 per cent copper, and 7 to 8 er cent ammonia. A small quantity of cane sugar is lso added. Its viscosity should be such that the time equired for 150 c.c. to flow through a short orifice 5 nm. wide from a tube 32 mm. wide and 280 mm. long, rovided with two marks indicating a volume of 150 c.c., will be 5 to 6 minutes. The solution should also be apable of forming a continuous thread, 2 meters long, efore breaking up into drops. This solution is passed hrough three filter presses in succession, the first being quipped with metal cloth having 1,200 meshes per q.cm., the second 1,400 and the third 1,500 meshes. It s finally filtered through asbestos cloth.

The glass capillaries used for spinning have an internal diameter of 0.16 to 0.20 mm. and are 2.5 to 4 mm. ong. A spinning pressure of 1.5 to 2.5 atmospheres is sed. Originally the precipitating liquid was 50 per ent sulphuric acid and the filament was washed on glass cylinders with a weak solution of ammonium acetate, followed by treatment with ammonia-soap solution at 50 deg. C. This method has since been superseded by alkaline precipitation. The bath contains 25 to 33 grams of caustic soda and 8 grams of glucose per 100 c.c. and is maintained at 48 to 50 deg. C. The threads are wound on glass cylinders, washed in water, passed through a bath containing magnesium or aluminum sulphate to displace the alkali, washed again and dried. The filaments making up one thread are now twisted with three turns to the inch and reeled. They still contain copper, and this is removed by washing the skeins in weak acid. After washing to remove the acid, the skeins are soaped and finally dried. Alkaline spinning gives a stronger and better thread.

The Thiele-Bemberg method is a modification of the one just described in so far as the spinning process is concerned. Instead of a fine capillary, spinning jets having an internal diameter of 0.8 mm. and a weak alkaline precipitant (2 per cent NaOH) are used. The filaments drop through a 50-cm. column of this liquid, which has a slow coagulating action, and are drawn out to very fine diameters by their own weight. It is said that dry diameters of 0.015 mm. may be thus obtained[7].

Viscose Process

Viscose silk, at this time probably the most important of the artificial silks, owes its origin to the work of Cross, Bevan and Beadle, who obtained a patent (Br. Pat. 8,700; 1892) for the preparation of a water soluble derivative of cellulose which they called viscoid or viscose. Stearn made this product available for the manufacture of filaments by patenting various precipitating agents (U. S. Pats. 622,087; 716,778; 725,016). Müller (U. S. Pat. 836,452) protected the present method of using a bath containing sulphuric acid and a sulphate.

The cellulose, whether woodpulp or linters, is transformed into its sodium compound by grinding with three times its weight of 17 to 18 per cent caustic soda in a wheel mill, and storing it in boxes for 48 to 72 hours. The same effect is obtained by mixing it with ten times its weight of the same strength caustic in a Werner & Pfleiderer mixer, permitting it to stand for 24 hours, and then centrifuging until the liquid content has been reduced to the same weight as in the previous method. It is then permitted to stand 48 hours more. To 400 parts of this mass (containing 100 parts of cellulose) in a rotating cylindrical mixer are added 60 parts of carbon bisulphide, and the mixing is continued for 1 to 3 hours at 15 to 30 deg. C. The excess of carbon bisulphide is then evaporated. The viscous mass is now dissolved in 54 parts of caustic soda and 300 parts of water in a W. & P. mixer and diluted until it contains 9 to 10 per cent of cellulose. The viscosity of the solution depends on the treatment of the raw cellulose as well as on the length of the alkali treatment. The solution is now filtered through cotton batting held between cotton cloths and permitted to age or mature at a temperature below 10 deg. C. until a sample gives an insoluble thread in 5 per cent formic acid. Originally the thread was coagulated by means of acid or ammonium salts. In present practice the bath is made up of 40 parts sodium bisulphate, 7 parts sulphuric acid and 60 parts water. The thread, made up of a number of filaments, may be crosswound on bobbins and washed and dried in this form. More frequently it is collected in the rotating cans previously mentioned (U. S. Pat. 702,382), washed in the form of skeins and dried under tension on reels[8].

Cellulose Acetate

Cellulose acetate silks are of more recent development. Mork, Little and Walker were among the first to patent their production (U. S. Pats. 712,200 and 792,149). Dried cotton linters are treated for several hours, gradually increasing the temperature from 15 to 40 deg. C., with 25 per cent acetic anhydride, to which about 1 per cent of sulphuric acid has been added. At the end of this time the mixture is diluted with 50 per cent acetic acid containing some sulphuric acid, and hydrolyzed for 3 hours at temperatures ranging from 25 to 70 deg. C. Cold water is then added to precipitate cellulose acetate, which is filtered off and washed free from acid. For the production of filaments the acetate is dissolved in a suitable solvent, such as glacial acetic or formic acid, chloroform, acetylene tetrachloride, and spun in a manner similar to those described into a precipitating bath. This bath may be water, if the solvent is miscible with water; or alcohol, benzene, etc., if it is not. The solvent and precipitant must be chosen in such a way that one will easily mix with the other and that the solvent will readily diffuse through the thin filament walls of the precipitated cellulose acetate.

Acetate silks are decidedly stronger than the other silks when wet. They have a very low electric conductivity and may displace natural silk entirely for insulating wires, etc. They cannot be dyed in the same manner as the other silks, but methods have been found to overcome the dyeing difficulties.[9]

Other Processes

Various other processes of artificial silk manufacture have been proposed at one time or another, but have

[7]Ost. *Z. angew. Chem.*, vol. 31, p. 141 (1918).

[8]Wilson, *J. Soc. Chem. Ind.*, vol. 36, p. 817 (1917).

[9]*J. Soc. Dyers & Colour.*, vol. 38, p. 162 (1922).

not been successful, although some of them have found temporary use. We merely mention gelatine (Vanduara silk), albumin, casein, macerated silkworms, natural silk solutions, solutions of cellulose in caustic soda, various acids and zinc chloride (filaments for incandescent carbon lamps).

Brief mention may be made of the manufacture of allied products, such as artificial horsehair, imitation fabrics, etc. For horsehair the solution of cellulose is spun through large openings and dried under small tension to get away from the too brilliant luster of silk, or the hair may receive a later treatment with oils. Artificial lace and tulle are made by passing a very viscous solution through engraved rolls into a precipitating bath. Remarkable effects can be obtained in this way. During the war Germany produced considerable quantities of so-called *Stapelfaser*, which was used as a substitute or admixture for wool. This is made by twisting artificial silk in the usual way, then cutting it into short lengths and spinning the resulting fibers, either alone or mixed with wool, just as cotton or wool is spun.

Properties

The specific gravity of artificial silk is about 1.51 whereas that of natural silk is only 1.36. Its moisture content under normal air dry conditions is about the same as for silk—i. e., 11 per cent. Acetate silk, however, under the same conditions contains only 2 to 3.5 per cent moisture. The diameters, according to Massot, compare as follows[10]:

Natural silk	0.0150 mm.
Chardonnet silk	0.0288 mm.
Lehner silk	0.0354 mm.
Glanzstoff	0.0295 mm.
Viscose silk	0.0305 mm.

Artificial silks swell when moistened, and in this condition the diameters are from 50 to 60 per cent larger. Advances in the art since the time of Massot's publication have made it possible to obtain much finer threads, closely approaching natural silk, as in the Thiele process previously mentioned and in Bronnert's work on viscose (U. S. Pats. 1,374,718; 1,376,671-2; 1,393,197-8-9).[11]

According to Strehlenert[12], the strengths of various natural and artificial silks compare as in Table I.

S. J. Pentecost[13] gives the figures of Table II.

TABLE I—STRENGTH OF SILKS

Variety	Strength, Kg. per Sq.Mm. Dry	Wet
Natural silks		
Chinese	53.2	46.7
French	50.4	40.9
French boiled off	25.5	13.6
French dyed red and weighted	20.0	15.6
French blue black, 100 per cent weighting	12.1	8.0
French black, 140 per cent weighting	7.9	6.3
French black, 500 per cent weighting	2.2	....
Artificial silks		
Chardonnet nitrocellulose	14.7	1.7
Lehner nitrocellulose	17.1	4.3
Strehlenert nitrocellulose	15.9	3.6
Glanzstoff	19.1	3.2
Viscose, Cross and Bevan	11.4	3.5
Viscose, latest	21.5	....
Cotton yarn	11.5	18.6

TABLE II—STRENGTH BY DENIERS

Type	Size in Deniers[14]	—Strength, Kg. per Sq. Mm.— Dry	Wet	Redried
Chardonnet	120	42	0	95
Glanzstoff	130	40	35	41
Viscose	120	51	50	51.5
Viscose	200	91	86	88

[14] In the trade, the fineness or "count" of silk is given in deniers, which is the weight, expressed in grams, of a thread 9,000 meters (Italian legal denier) or 10,000 meters (metric denier) long.

It will be noted that in Strehlenert's figures the artificial silks compare favorably with dyed silks, especially if the latter have been weighted to any extent. Here again, numerous advances have been made and the strengths of artificial silks have been improved.

Distinguishing Silks

Methods of distinguishing between the various kinds of artificial silks are given by Maschner[15]. About 0.2 gram of the sample in a test tube is covered with concentrated sulphuric acid. Copper silk turns yellow at once, changing in a few minutes to a yellowish red. Within half an hour it dissolves, coloring the acid a pale yellowish brown. Viscose silk turns to reddish brown in 1 or 2 minutes and dissolves to a brown liquid. Concentrated phosphoric acid of 1.7 sp.gr. turns copper silk that has been spun in alkali, brown, whereas it gives no coloration with copper silk spun in acid, nitrocellulose or viscose silks. Known samples should be subjected to these tests at the same time as the unknown to make sure of the colors. Nitrocellulose silk, owing to traces of undecomposed nitric acid esters which are always present, gives a dark blue coloration with a solution of diphenylamine in concentrated sulphuric acid.

Comparison of the cross-sections under the microscope is probably the best method for distinguishing between natural and artificial silks. A rough test that may, however, be masked by dyeing is to burn a thread of each. Silk will give the characteristic odor of burning nitrogenous matter. According to Formhals[16], the samples to be tested are dissolved in concentrated sulphuric acid, diluted with water and then made alkaline. A solution of diazotized paranitraniline is now added. Natural silk under these conditions will give a red, artificial silk a yellow color. It is claimed that this test may be used successfully even in the case of heavily weighted, dyed silks.

It would lead too far to go into the dyeing of artificial silk. Suffice it to say that in general it has a greater affinity for dyestuffs than cotton. This does not apply to acetate silk, where special methods have to be used to fix the dyestuffs on the fiber. Specific instructions for the different cases may be obtained from the dye manufacturers.

Uses of Artificial Silk and Its Consumption in the United States

Since artificial silk first came on the market its uses have rapidly increased. It has been improved to such an extent that it can be used in a great many cases in place of silk. Where there is considerable strain on the fabric, it is generally woven or knitted with a thread of silk or cotton. The largely increased production of artificial silk has apparently had no influence on the consumption of the natural product. Artificial silk must be considered as a new textile material rather than as a substitute for an old one; it has made a place for itself in many fields, and there is ample room for both. In 1899 the consumption of artificial silk in the textile mills of the United States amounted to 6,056 lb., of a value of $10,380. Table III shows how it has grown in importance since that time.

Wilson[17] estimates the present daily production of

(f) Up to 1912 artificial silk imports were included with silk figures.

artificial silk to be from 5 to 6 tons in Germany, 4 tons in France, 10 tons in England, with smaller quantities produced in Belgium, Switzerland and Italy. The estimate for Germany is believed to be low. The capacity in this country is probably about 45,000 lb. daily for viscose and 7,000 lb. for nitrocellulose silk.

Processes Used in Different Countries

It is interesting to note that nitrocellulose silk, which had its origin in France, has been most successful there and in Belgium. Cuprammonia silk, developed largely in Germany, has had its greatest success in that country, although the branches of the Glanzstoff A. G. have prospered in other countries. England and the United States have more or less confined themselves to viscose, which was discovered by Englishmen. The German viscose plants of Count Donnersmarck have never been successful and were sold to the Glanzstoff people a few years before the war. Owing to the scarcity of cotton, copper and ammonia during the war in Germany, the Germans turned to the manufacture of viscose silk in spite of the success they had previously had with cuprammonia. Of the nitrocellulose factories, the Belgian plant at Tubize has been signally successful, owing perhaps to a favorable and cheap supply of alcohol. Foltzer, in his book on "Artificial Silk and Its Manufacture," gives the following comparative cost figures for artificial silk:

Nitrocellulose	13.55 fr.	= $2.61 (at par of exchange)
Cuprammonia	8.85 fr.	= $1.71
Viscose	8.25 fr.	= $1.59

Solvents recovery has since been improved so that at this time the cost of nitrocellulose silks is relatively lower.

In the United States today three processes are in use—viscose, nitrocellulose and acetate. Of these viscose is the oldest, having been started in Lansdowne, Pa. (later Marcus Hook, Pa.), in the early years of this century. The nitrocellulose plant is the youngest, having been built in 1921. Cellulose acetate still seems to be in the experimental stage and but little of it is on the market. Cuprammonia has never established a foothold here, though a number of small plants have been started from time to time for its production. The failures seem to have been due to lack of capital or inexperience in the mechanical handling of the product. On the other hand, this type has been very successful in Germany and other places where the original manufacturers established branches and large quantities were imported and used here before the war. There seems to be no reason why it should not be made successfully in this country, as the raw materials—cotton, copper and ammonia—are available in large quantities and at prices as low as or lower than elsewhere. With an efficient recovery, it is decidedly cheaper to manufacture than nitrocellulose silk and should cost little if any more than viscose silk. It has a higher luster than either and has no tendency to yellow or deteriorate in storage.

The artificial silk industry is one of the few that have suffered little from the business depression prevailing during the past 2 years, and promises to maintain its status as an important branch of the textile and chemical industries.

Thermal Conductivity of Refractories*

By W. A. Hull
Physicist, U. S. Bureau of Standards

IN CONNECTION with the work of A.S.T.M. committee C-8 on refractories, and particularly with that of the sub-committee on thermal conductivity, it seems worth while to consider, briefly, the relation of thermal conductivity to other properties of refractories and to attempt to find what place, if any, this property will have in specifications for refractories. It may also be worth while to try to determine what is most needed in the way of data and of methods of test.

Factors of Importance in Refractory Specifications

In practically all the uses to which refractories are put, the most essential requirement is that they shall resist destructive agencies, including heat, erosion, the chemical action of the constituents of furnace gases and the corrosive action of slags and glasses. No single type of material will resist all the destructive agencies successfully; neither are all the destructive agencies found in any one furnace. The primary purpose of a specification is to state, quantitatively, the properties which a refractory material must have in order to resist, for a reasonable length of time, the destructive agencies which will be encountered in a specific place in a particular type of furnace.

In general, only one type of refractory material is suitable for a given purpose. Most of the high-temperature furnace work calls for high-grade fireclay brick; for certain conditions, silica refractories are practically always used, and other conditions require still other types. It has been sufficiently well established that the difference in thermal conductivity between different brands or grades of brick within a given type or class are not important as compared with differences in refractoriness, in resistance to spalling, resistance to slag corrosion, etc. It seems probable, therefore, that in the great majority of cases those properties which are essential to resistance to destructive agencies and which vary to an important extent from one brand of brick to another will be made the matters of specification regardless of thermal conductivity.

There are cases, however, in which the selection of the *type* of refractory to be used for a given purpose is influenced by the relative conductivities of different types, and in cases of this sort, where more than one type is available and the conductivity is especially important, heat conductivity may eventually become a matter of specification.

Reliability of Available Thermal Conductivity Data

Since thermal conductivity may be a factor in the selection of the type of brick to be used for a given purpose, it is important to have reliable data as to the conductivity of the different refractory materials and it may be worth while to consider the completeness and the reliability of the figures now available.

Unfortunately, the figures given in many of the tables to be found in handbooks and elsewhere have been taken from unsatisfactory sources and are somewhat confusing. This applies particularly to the data obtained from the investigation by Wologdine,[1] which were for a number of years (1909-1915) the best data available on the heat conductivity of refractory materials and have, in consequence, been very extensively quoted. However, it is difficult, in going over Wologdine's results, to find record of a single group of specimens that appears to have been burned to the temperature to which the material would have been burned commercially; it appears to have been the purpose of the investigator to show the effect of the temperature of burning on the conductivity of the various materials rather than to provide data for the use of engineers and others who might have occasion to estimate heat losses in connection with the design of furnace installations.

In 1915 important work on thermal conductivity of refractories was reported by one American[2] and a group of British[3] investigators. The work of Dudley has much to recommend it. His determinations were made on large specimens built up from several full-size bricks and he used well-known American brands of firebrick, thereby establishing the identity of the materials on which his conductivity determinations were made. His description of his method indicates that his work was done with what may be termed good engineering accuracy.

The work done by Dougill, Hodsman and Cobb appears to have been well planned and skillfully executed. Their method permitted the use of commercial bricks, made and burned in the regular way. While their determinations were not made on the same brands of brick as Dudley's, they included approximately the same classes of refractories that he tested and a comparison of those results which are comparable, from

* Cal. per sec. per sq.cm. for a temperature gradient of 1 deg. C. per cm.

A—"The Thermal Conductivity of Refractories," by Boyd Dudley, Jr., *Trans. Am. Electrochem. Soc.*, vol. 27, p 285 (1915)

B—"The Thermal Conductivity of Refractory Materials," by G. Dougill, H. J. Hodsman and J. W. Cobb—*J. Soc. Chem. Ind.*, vol. 34 (1915).

nese two investigations, given in Table I, shows as ose agreement as could be expected. While most of heir results are expressed as the mean k for the speci- hen under the temperature conditions existing in it at he time the determination was made, both Dudley and)ougill, Hodsman and Cobb computed, from their data, he coefficients of thermal conductivity of some of the naterials which they investigated, for different tem- eratures up to 1,000 deg. C. Dougill, Hodsman and Cobb deduced the following formulas:

1) For fireclay brick,

$$k_t = 0.00155 + 0.25 \times 10^{-5}t$$

2) For magnesia brick,

$$k_t = 0.0285 - 0.379 \times 10^{-4}t + 0.179 \times 10^{-7}t^2$$

n which k_t is the thermal conductivity at temperature t.

Application of the Data in Calculating Heat Transfer

All things considered, it seems entirely reasonable to ccept results of these investigations and to make use f the formulas of Dougill, Hodsman and Cobb in rdinary engineering computations, making allowance or the fact that the values will be lower in the case f porous, light-burned brick and higher with denser rick. It is true that only rough estimates can be btained in this way, but it must be taken into con- ideration that only rough estimates of the heat trans- er through the walls of a given installation could be btained by computation, in most cases, even though recise figures for the thermal conductivity of the fire- rick were available. In the first place the temperatures f the inner and outer surface must be known and if the wall is to be more than one brick thick, the effect of the joint, or joints, must also be known as well as the con- uctivity of the refractory material, before the heat flow through the wall can be computed. Unless the tempera- tures of the two surfaces can actually be measured, a rough approximation is introduced at this point. The effect of joints must not be overlooked and introduces another factor that is uncertain as to magnitude.

Effect of Other Factors—Surface Resistance

Furthermore, it must be taken into consideration that heat conductivity, or its reciprocal, resistance to heat flow, is but one of several factors, working in series and that the larger the other factors, such as surface resistance and the effects of joints, the smaller, relatively, is the effect of differences or errors in the values assumed for thermal conductivity. The effect of surface resistance is shown in the operation of re- torts, in a gas plant, by the fact that when the flame changes from transparent to luminous the rate of gas production increases, showing that heat is passing into the retorts more rapidly. When the flame is transparent a very large portion of the heat must be taken up by the retort by conduction; when the flame becomes lumi- nous, radiant energy is transferred rapidly from the myriad of minute particles of incandescent carbon float- ing in the gas to the surface of the retort, and the retort is heated by radiation, reducing to a large extent, the effect of the surface resistance at the outer surface. The fact that the difference in rate of production is con- siderable shows that the surface resistance is a large factor. This factor has been studied sufficiently to jus- tify the statement that the surface resistance of one surface of a retort may be as great as the internal re- sistance of the wall itself.

There is one other factor that should not be lost sight of in this connection. In the case of furnaces operating at high temperatures, there is a tendency for a portion of the brick to vitrify, in course of time, increasing the conductivity of that portion by possibly 40 to 50 per cent. Also, under certain conditions, re- fractories become impregnated with various substances taken up from the gases penetrating them and it is practically certain that the impregnated materials differ to an important extent in heat conductivity and in other properties from the original material.

It is not the purpose of the foregoing discussion to discourage the making of computations, but it is thought that some computers may believe, erroneously, that the lack of reliable figures for thermal conduc- tivity is the greatest obstacle in the way of obtaining reliable estimates of the heat transfer to be expected in a given case, whereas, as a matter of fact, the more one studies the problem the less concern is felt about the accuracy of the value ascribed to the conductivity of the material in question; other factors which neces- sarily enter into the computation have to be approxi- mated so roughly that the uncertainty involved in this one becomes relatively unimportant.

Need for Simple Standard Method

The fact remains, however, that in certain places, particularly in muffles and retorts, high conductivity is important because it is essential to efficiency, whereas in others, particularly in the insulating courses that are used in certain conditions, back of refractory lin- ings, low conductivity is important for the same reason. With the advent of carborundum and other high con- ductivity refractories, as well as the introduction of new insulating materials, an increasing interest is be- ing taken in the heat conductivity of refractories and it is important that a standard method for making conductivity determinations should be developed. The method should be simple so that routine tests can be made, with apparatus of moderate cost, with reasonable accuracy, by an operator of reasonable ability and ex- perience. It would be a waste of time to make conduc- tivity determinations with great precision on samples of firebrick, because the properties of different samples, even of brick of the same brand, would vary some- what. On the other hand, it is essential that any method adopted be capable of giving results that can be depended on for reasonable accuracy, say to about 5 per cent.

In answer to the question which naturally arises, in this connection, as to what the Bureau of Standards is prepared to contribute in the way of a suggested method, it may be said that the bureau has been work- ing for a number of years on the determination of thermal conductivity, the earlier work being done at low temperatures. Data obtained from this work are to be found in an article entitled "Thermal Conductiv- ity of Heat Insulators," by M. S. VanDusen, in the *Journal* of the American Society of Refrigerating En- gineers, November, 1920, and the *Journal* of the Society of Heating and Ventilating Engineers, October, 1920. Work is now nearing completion on a method for the ac- curate determination of the conductivity of refractory materials. While this method will not be adapted to the making of appropriate determinations in a rou- tine way, it is believed that the knowledge and experi- ence that have been gained in connection with the more

refined work that has been done will make it possible to develop a test method which will be suitable for such use.

SUMMARY

The situation in regard to heat conductivity may be summed up as follows: Differences in thermal conductivity between different brands or kinds of refractory materials within a given class, such as high-grade fireclay refractories, while they may be considerable, are comparatively unimportant so far as the efficiency of an installation is concerned, because the conductivity of the material constituting a wall is only one of several factors working in series, to affect rate of heat transmission. Thus a 10 per cent difference in conductivity may make only a 5 or a 2 per cent difference in the heat flow through a wall. On the other hand, the difference in conductivity between two types of materials such as fireclay refractories and carborundum refractories may be relatively important for such purposes as the walls of retorts and muffles. It is not unreasonable to expect that conductivity will become a matter of specification for refractory materials for certain purposes.

In regard to the question of obtaining satisfactory figures for use in computing heat flow through walls of various types in furnaces, attention is called to the fact that while the data of Wologdine, which have been copied extensively in physical tables, are likely to be misleading unless his work is discriminatingly studied, the data of Dudley and of Dougill, Hodsman and Cobb appear to be satisfactory for ordinary purposes. These investigators made determinations on well-known commercial materials and their results check as closely as should be expected, considering the fact that the materials studied were not identical. The data from these investigations should be satisfactory to the engineer, considering the fact that he must accept rough approximations for other factors involved in computations of heat transfer through walls.

The different investigators who have made heat conductivity measurements have developed a variety of methods, all of which are elaborate and laborious. There is a need for a standard method for making routine conductivity tests of commercial materials. It is not essential that it should be a precision method, but it is important that it be simple and reasonably convenient and at the same time accurate, within reasonable limits.

Hygroscopicity of Tetryl and Tetranitraniline

At the Pittsburgh, Pa., experiment station of the Bureau of Mines, a study is being made of the hygroscopicity of tetryl and tetranitraniline. The purpose of the investigation is to determine the physical constants of pure chemicals and the commercial products as used in the manufacture of explosives. The work is being done by L. G. Marsh, under the general supervision of C. A. Taylor, both assistant explosives chemists.

Chinese Pig Iron Production

Commercial Attaché Arnold, Peking, reports that, according to the estimate of K. Y. Kwong, Chinese engineer and mining authority, China's total production of pig iron annually is about 450,000 tons from Chinese furnaces and 250,000 tons from Japanese furnaces in China. The total output of iron ore in China is about 2,000,000 tons a year.

Industrial Ventilation as Applied To Dust and Fume Removal*

BY H. M. NICHOLS† AND F. R. ELLIS‡

TO QUOTE an official of one of the leading insurance companies: "Industrial or occupational diseases are becoming recognized more and more completely as being compensatable. That is to say, the insurance carriers (and therefore the employers, since they have to pay the insurance costs) now have to consider not only the obvious immediate injuries to employees from hazards such as burns from corrosive fumes or deaths from explosions of combustible dusts and vapors, but also the indirect and sometimes slow-acting internal injuries to employees, such as lead poisoning and other toxic actions in human organs and tissues."

It is, therefore, becoming a matter of economy as well as humanitarian to control these agencies so that they will not endanger the health of the workers, and mechanical ventilating systems play an important part in such control.

General Method of Arranging Mechanical Ventilation

The necessity for ameliorating the conditions created by machines producing irritating dust was recognized long before the days of liability insurance or of workmen's compensation legislation; in fact, the beginnings of the fan business were inspired by the necessity of finding some way to get rid of the irritating dust from buffing machines in the shoe industry. It was for this purpose that B. F. Sturtevant, the father of the industry, about 1860 conceived his first fan.

The treatment of this form of hazard—namely, all processes producing fine, irritating dusts from wheels or cutters—is today very much the same as the arrangement evolved in the application of this first fan. In this class come buffing, grinding and polishing wheel operation. Many classes of cutting operations may be treated in a similar manner.

Inclose Wheel of Cutter as Completely as Possible

In general, the wheel or cutter is as nearly wholly inclosed as possible by a metal hood which is attached to and becomes a part of the piping of the exhaust system; the hood should be designed to take advantage of any movement given the dust by the operation. Thus, if a cutter throws the dust in a horizontal direction, the hood should be so arranged that the dust will be thrown into it. Where the material is thrown vertically upward or downward, the hood should be placed above or below the wheel or cutter. It is obvious that by carrying away the dust in the direction in which it is thrown the trapping and removal of the material will be the most effective.

It was only a small step from the removal of dust-buffing operations to the removal of refuse from woodworking machinery, and while many woodworking operations do not produce refuse in a finely divided state, the handling of this class of machinery is very similar to the method of handling buffing machinery.

Shrinkage and Expansion Of High-Speed Steel Due to Heat-Treatment

Volume and Hardness Changes, Thermal Analysis and Microstructure Indicate That Secondary Hardness in High-Speed Steel Is Due to Decomposition of a Stable Austenite Into Martensite II, Different From Martensite Formed During Quenching

By Marcus A. Grossmann
Metallurgist, Electric Alloy Steel Co., Charleroi, Pa.

TESTS described herein were recently undertaken primarily to obtain data on the amount which should be allowed in high-speed tools for shrinkge or expansion resulting from heat-treatment. The esults obtained seem to throw an interesting sidelight n the nature of the reactions taking place during the eat-treating of high-speed steel.

Method of Testing

Tests were carried out on a high-speed steel of the ollowing analysis: Carbon 0.65 per cent, tungsten 18.0, hromium 4.0, vanadium 1.0. Cylinders 1½ in. diameter nd about 2½ in. long were heat-treated and the changes n length noted. In all the earlier tests the pieces were laced in a semi-muffle gas furnace without protection n the ends. Therefore, due to the formation of scale, o direct comparison of the annealed to the hardened tate could be obtained. Instead, the scale was ground ff and a measurement taken in the hardened condition; he pieces were then drawn at successively higher temeratures and measured after each draw. Finally the amples were annealed, oxidation being kept as low as ossible. The final dimensions (after annealing) were ssumed to be the same as those of an annealed piece efore hardening. Later a method of clamping proecting pieces on the ends of the test-pieces was devised, vhich allowed the test-piece to be hardened at temperaures as high as 2,400 deg. F. without any visible xidation. Measurements could then be taken directly n both the annealed and the hardened condition. All neasurements were made with ordinary micrometers.

Heat-Treatment

In hardening, the test-pieces were preheated for about 15 minutes at about 1,550 deg. F. and were then heated o the temperature indicated on the graphs. In each ase they were heated just to the temperature for quenching and then quenched in oil. The samples were measured as quenched and were then measured after ach successive draw, each value shown in the table being an average of from four to six readings. Care was taken that the samples were measured always at the same temperature—about 70 deg. F. Drawings up to 600 deg. F. were done in oil; beyond that temperature the drawings were done in a lead bath covered with charcoal or in molten sodium-potassium nitrate. As soon as the specimen had been held the required time in the drawing bath it was immediately quenched in cold heavy oil in order to avoid excessive oxidation. It was not believed that this quenching had any effect on the dimensions inasmuch as the steel did not go through any transformations when being quenched from the drawing temperature, and the temperature gradient due to quenching could scarcely have been great enough to cause the steel at any point to exceed its elastic limit during the quenching. (For discussion of this point see Heyn, "Materialienkunde," Chap. VI, Section D.)

Observations

Examination of Fig. 1 shows that regardless of the quenching temperatures there is a certain regular trend of the contractions and expansions on reheating which in general vary in amplitude but not in direction. (It may be well to repeat here that all measurements were taken after the steel had cooled to room temperature, 70 deg. F. Therefore when, for example, a "contraction on heating" is mentioned, this refers to the comparative dimensions of the cold test-pieces after cooling from the heating temperature, and takes no account of the intervening normal thermal expansion in the heating process, which has no especial relation to the structural changes.) When the quenched steel was reheated slightly and then cooled, a contraction resulted; after further heating at higher temperature it showed a larger shrinkage until a drawing temperature of about 1,000 deg. F. was reached. Drawing to higher temperature (1,050 deg. F.) then caused an expansion which was only very moderate, but which became very marked after reheating to about 1,100 deg. Drawing beyond this temperature again caused a contraction, which continued until the steel was fully annealed.

Howard Scott[1] shows a figure giving practically the same shape curves as those shown in Fig. 1. After quenching at 1,940 deg. F. (1,060 deg. C.) his curve representing drawing temperature versus density shows uniform shrinkage after a draw up to 750 deg. F. and then a slight expansion after a draw at 1,100 deg. F.

It will be observed that as the quenching temperature

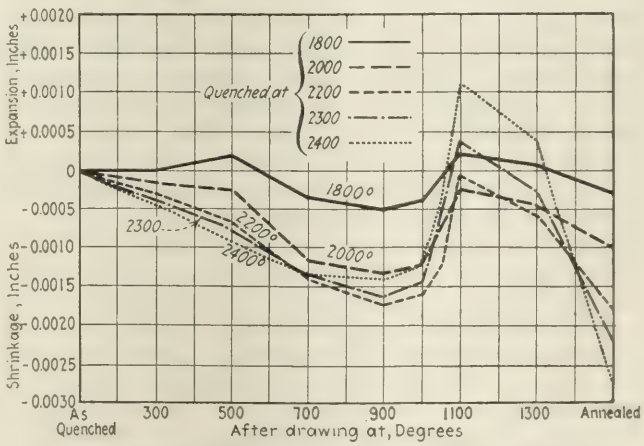

FIG. 1—MEAN VARIATIONS IN LENGTH OF 2.5-IN. SAMPLE OF HIGH-SPEED STEEL

[1]Bureau of Standards Scientific Paper 395, "Relation of the High-Temperature Treatment of High-Speed Steel to Secondary Hardening and Red-Hardness."

was raised, the amount by which the steel expanded on hardening increased (compare the location of the curves at the ordinates marked "As quenched" and "Annealed"). The amount by which the steel contracted after the low draws also increased. It will be observed that with this rise in quenching temperature, the amount by which the steel expanded after a draw in the neighborhood of 1,100 deg. F. also increased. Subsequent contraction, after the drawing temperature of 1,100 deg. was passed, was of course also greater as the quenching temperature was raised.

It appears that these shrinkage measurements throw further light on the reactions inferred from the hardness curves for drawn high-speed steel (Fig. 2) as well as the deductions from the microstructure and from the critical points shown in cooling and heating curves.

Hardness, Microscopic and Thermal Investigations

It is proposed to review rather briefly the evidence of other lines of investigation, and then to show how a series of shrinkage curves presents a general picture of all the reactions taking place in a high-speed steel. Shrinkage curves offer as yet no evidence as to the composition of the phases taking part in these reactions, but it is believed that with further refinement this, too, may be forthcoming.

Probably the earliest studies along these lines were in the field of hardness. Fig. 2 summarizes the results of numerous series of hardness measurements on steel of the composition under discussion. It will be seen that if we consider the steel as quenched but not drawn, there is an increase in the scleroscope hardness with rise in quenching temperature, up to a certain quenching range, beyond which no appreciable increase in hardness is produced. When these quenched pieces are drawn, there is a gradual decrease in the hardness, which decrease continues up to drawing temperatures of 900 to 1,000 deg. F. After the steel has been drawn in the neighborhood of 1,100 deg., there is an increase in hardness, which is very pronounced for steels previously quenched from the highest temperatures, but which is in evidence merely as a flattening of the curve at the low quenching temperatures. For still higher drawing temperatures the hardness finally decreases, approaching that of the annealed condition.

From these hardness curves it seems that as the quenching temperature is raised some hard constituent or constituents are formed, whose amount increases with this rise in quenching temperature. When the steels are drawn, some change takes place up to 1,000 deg. which is responsible for a decrease in hardness. After drawing at 1,100 deg., there is an increase in hardness which may be attributed most reasonably to the appearance of a new constituent. On heating at still higher temperatures, all the constituents are finally brought to the annealed condition.

Let us consider next the microscopic evidence. After quenching from the lowest temperatures the pieces show for the most part merely a gray mottled background, containing larger particles of what are considered to be carbides and tungstides. As the quenching temperature is raised, there gradually becomes distinguishable in the gray background of the cold samples a polyhedral structure of what appears to be a new constituent. As the quenching temperature is raised further, the new grains become more distinct and increase in size, and the comparatively large particles of carbide and tungstide decrease in size and number, being apparently dissolved to make up part of th new constituent. Now this new constituent has bee called austenite, from the fact that when a piece showin it is drawn at 1,100 deg., it develops the characteristi structure of martensite. Since martensite found in car bon steels is very hard, it is reasonable to suppose tha the martensite in high-speed steels is a very har constituent, even though it may be of different chemica composition from the martensite of carbon steels. Thi would account for the hardness developed by drawing a 1,100 deg., which is commonly called "secondary hard ness." On heating the hardened steel beyond 1,100 deg the martensite structure is broken up and the stee returns gradually to the obscure uncertain structur of the annealed condition.

Let us now consider the time-temperature curve found in thermal anaylsis, of which good examples ar those developed early by Yatsevich and reproduced b Sauveur in his "Metallography and Heat-Treatment o Iron and Steel," on p. 358. When the highest tem perature reached is but slightly above the critical range (say at 1,600 deg. F.) there is a pronounced jog in the

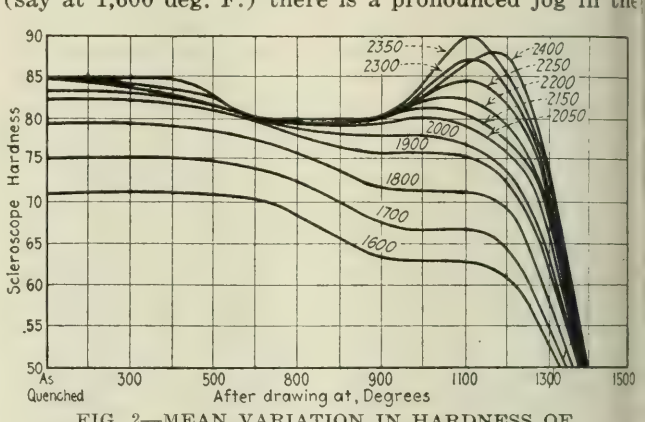

FIG. 2—MEAN VARIATION IN HARDNESS OF HIGH-SPEED STEEL

cooling curve at about 1,350 deg. F., which corresponds to the transformation from austenite through martensite to troostite. With rise in the temperature to which the steel is heated for taking the cooling curve this transformation at 1,300 deg. decreases in intensity, but there appears a second transformation at about 800 deg. F. This lower transformation, which the writer interprets as a transformation of austenite to martensite, increases in intensity as the initial temperature is raised. The increase in intensity of this martensite transformation naturally indicates an increase in the proportion of martensite in the cooled steel. (This would account partly for the increase in hardness with rise in quenching temperature, but involves the assumption that the microscopic appearance called austenite existing in these highly quenched steels is not really and entirely a solid solution of the various constituents.) If we now turn from the cooling curves to the heating curves, we find on reheating a piece which has been quenched from a high temperature and which is therefore apparently "austenitic" in the microstructure that there is a slight evolution of heat at 1,100 deg. F. This is thought to represent the transformation of some remaining austenite to a second kind of martensite, which also becomes evident in the hardness curves and finally appears in the microstructure.

Shrinkage Evidence

We come now to the evidence found in the shrinkage curves. These measurements, when considered in con-

lection with other lines of investigation, present a lear picture of the reactions taking place in heat-reatment.

It must be borne in mind that volume changes induced by heat-treatments may be the result of a combination of at least two factors: (1) The expansion which akes place during the transformation from austenite o martensite, and (2) the contraction which occurs after heating martensite, which is generally supposed o be connected with the formation of carbide molecules and crystals from elemental iron and carbon, but which the present author conceives as due in some measure also to grain growth. The contraction observed after drawing high-speed steel appears to be the same phenomenon as that observed by Andrew, Rippon, Miller and Wragg[2] which is discussed also by McAdam.[3]

We find first of all that as the quenching temperature is raised the difference in volume between the quenched and the annealed condition increases—that is, the expansion on quenching increases. This corresponds very satisfactorily to the increase in the amount of "primary" martensite, indicated in the cooling curves by the increasingly prominent discontinuity at about 800 deg. F., and in the hardness measurements by the increase in hardness as the quenching temperature is raised.

TABLE I—DIFFERENCE IN LENGTH BETWEEN DRAWN PIECES AND THE ORIGINALS QUENCHED AND NOT DRAWN.

	Drawing Temperatures, Deg. F.			
Steel	800	1,050	1,100	Subsequent 800
Annealed control piece...	—0.0001	—0.0001	0	+0.0003
	—0.0001	—0.0001	0	+0.0002
Quenched at 2,300 deg....	—0.0016	—0.0010	+0.0001	+0.0008
	—0.0016	—0.0012	+0.0003	+0.0007

When this quenched steel is now drawn to temperatures below 1,000 deg. F., the resulting contraction corresponds to the formation of carbide and grain growth in this "primary" martensite formed on quenching. The higher the quenching temperature the greater is this contraction on drawing; this was to be expected because of the presence of a greater amount of martensite which can be decomposed. This contraction, in being attributed to the decomposition of martensite with grain growth and formation of carbides, corresponds satisfactorily to the decrease in hardness of hardened high-speed steels after drawing at temperatures below 1,000 deg. F. This reasoning is based on the considerations presented in Jeffries' slip interference theory of hardening.[4]

After drawing hardened high-speed steels at 1,100 deg. F. there is then a second expansion which corresponds to the formation of a second martensite indicated by the hardness curve, the microstructure and the thermal curves. The expansion at 1,100 deg. acts in the manner which was to be expected. It also points out in a striking manner that the formation of a "secondary" or stable austenite begins soon after the critical point in heating has been passed, because quenching temperatures as low as 1,800 deg. F. induce a marked expansion after drawing at 1,100 deg. The amount of this expansion increases as the quenching temperature is raised until at quenching temperatures in the neighborhood of 2,300 to 2,400 deg. F. the expansion is very considerable.

It should be pointed out here, and the author wishes to lay emphasis on this point, that it seems inappropriate to refer to the two kinds of martensite formed in high-speed steel by the same name. The probability that they are not the same type of martensite and therefore probably not derived from the same type of austenite was indicated by a separate set of shrinkage measurements. If the martensite formed from the stable austenite by reheating at 1,100 deg. were of the same kind as the martensite formed in quenching, it would behave in the same way and would therefore decompose and show a shrinkage at the same temperatures. The values given in Table I show that the pieces hardened at 2,300 deg. and drawn at 1,100 deg. did not shrink on subsequent reheating up to temperatures of 850 deg. The new martensite is thus much more stable and holds its hardness better than does the "primary" martensite. It is therefore proposed to call the martensite formed on quenching "martensite I" and the martensite developed by subsequent tempering of the austenite "martensite II." It is this martensite II which can be seen readily under the microscope, for after the proper hardening and tempering procedure, martensite II is very coarse. Martensite I is a much less stable material than martensite II and corresponds more to martensites formed in carbon steels or low alloy steels, which are softened by comparatively low drawing temperatures. Martensite II, on the other hand, is the structural constituent which when developed gives to high-speed steel its most valuable high-speed cutting properties.

Constitution of High-Speed Steel

A general conception of the constitution of high-speed steels in the hardened condition is offered as follows:

It appears that there are present in the hardened steel before it is drawn the three structural constituents troostite, martensite and austenite. In addition there are certain tungstides and carbides, which are present as comparatively coarse granules if the quenching temperature was not high. With a very moderate quenching temperature—1,700 deg. F.—the amount of troostite is quite large, while the amounts of martensite and austenite are very small. As the quenching temperature is raised, the amounts of martensite and austenite increase with a corresponding decrease in the amount of troostite. At the same time it is evident that the absorption of tungstides and carbides increases, with the resultant formation of more austenite of a very stable character existing after quenching and changed only with difficulty to martensite—namely, by reheating to temperatures of 1,100 deg. F. and above.

Formation of martensite I is seen on the cooling curves of Yatsevich in the evolution of heat at about 800 deg. F. in cooling. Its presence is deduced from the shrinkage curves by the expansion on hardening and by the contraction of the steel after tempering up to temperatures of 1,000 deg. F. It makes its presence felt in the hardness by the increase in hardness of the quenched pieces as the quenching temperature is raised (see Fig. 2) and also by the decrease in hardness caused by the decomposition of this primary martensite after drawing the hardened steel at temperatures up to 1,000 deg. F. Formation of this martensite I increases at first rapidly with increase of quenching temperature,

[2] *Journal Iron and Steel Institute*, 1920—I, p. 527.

[3] *Chem. & Met. Eng.*, vol. 25, p. 613, Sept. 28, 1921.

[4] *Chem & Met. Eng.*, vol. 24, p. 1057, June 15, 1921. The slip interference theory fits observed facts so well that the present writer considers it to be completely established. It has served as the background of reasoning for the present paper.

but in the higher ranges of temperature above 2,100 to 2,200 deg. F. further increase in the quenching temperature does not seem to have proportionately as great an effect.

Existence of austenite in highly quenched samples is indicated in the time-temperature heating curves by the transformation (to martensite) when reheating quenched samples at 1,100 deg. F. The increase in the amount of stable austenite with quenching temperature is very evident both in the hardness curves and in the expansion curves, since its presence is deduced from the resultant formation of martensite. When the quenched samples are drawn at 1,100 deg. F., the increase in scleroscope hardness is very marked, especially after a quench in the neighborhood of 2,300 deg. F., as shown in Fig. 2. Expansion due to the appearance of this martensite also appears very plainly at 1,100 deg. F. (Fig. 1). This stable martensite II is decomposed only by subsequent heating at temperatures higher than 1,100 deg., which causes the final contraction of the steel and its return ultimately to the dimensions of the annealed condition.

Change of Properties of Substances on Drying

By Ellwood Hendrick

IN THE lively speech of Prof. H. E. Armstrong at the Glasgow meeting of the Society of Chemical Industry, he referred with great gusto to the work of Prof. H. B. Baker of the Imperial College of Science and Technology. We think his enthusiasm was warranted. A short record of Professor Baker's latest work has been published in the *Transactions* of the Chemical Society (London) for the current year (vol. 121) and for the benefit of our readers we shall review it adding few comments.

The title is "Change of Properties of Substances on Drying" and the significance of his findings will soon appear. Back in 1912 he observed that the boiling points of trioxide and tetroxide of nitrogen were raised respectively 44 and 47 deg. when they were permitted to stand for a long time in contact with phosphoric oxide. The following year he prepared a number of other liquids in a high state of purity, and sealed them up in vessels containing specially purified phosphorus pentoxide, with a view of getting them as dry as possible. Then came the war and the extraordinary duties involved in it, so that the substances Professor Baker had set aside for special drying in this way were left untouched for from 8 to 9 years. When the war was over and the opportunity for research returned, he proceeded to determine the boiling points of these very dry liquids, and he obtained surprising results, very similar to those noted in 1912. That is, the boiling points had gone up from 14 to 60 deg. above normal, although the boiling, when it did take place, was indicated by the formation of bubbles in the heated liquid in each case, and it proceeded quietly, with no sign of the violent ebullition which accompanies the breaking down of a superheated condition. Broken pieces of silica had been placed beforehand in each bulb to prevent superheating. In some cases two thermometers were inclosed in the bulb, one dipping in the liquid and the other suspended about 3 cm. above its surface. The temperatures read in the latter were at most 2 deg. above the normal boiling point of the liquid, and yet when the condensed liquid from the distillation was again heated it did not boil until the high temperature had been reached.

The following table shows the results of Professor Baker's tests:

	Period of Drying, Years	Original Boiling Point, Deg.	New Boiling Point, Deg.	Rise, Deg.
Bromine	8	63	118	55
Mercury	9	358	420–425	62
Hexane	8½	68.4	82	14
Benzene	8½	80	106	26
Carbon bisulphide	1 plus 27	49.5	80	30
Carbon tetrachloride	9	78	above 112	34
Ethyl ether	9	35	83	48
Methyl alcohol	9	66	above 120	54
Ethyl alcohol	9	78.5	138	60
Propyl alcohol	9	95	134	39

The apparatus used consisted in part of a glass distilling flask with two side tubes. To one of the side tubes was sealed the single side tube of another distilling flask, while the second side tube of the first was drawn out to a long, bent-down tube of about 2 mm. diameter. The necks of both flasks were lengthened by sealing on tubes of similar diameter, which were bent over at the top to form convenient receptacles for the phosphoric oxide. The apparatus was washed and dried thoroughly according to details given, and fragments of fused quartz previously heated were placed at the bottom of each flask. After the introduction of the liquids all openings were sealed and the drying process proceeded for the long period of time provided by the interim of the war and its more pressing duties. With liquids from which no chemical action on the phosphoric oxide was to be feared, such as benzene, hexane or bromine, a plug of the drying agent was placed with the liquid in the flask that contained it. In other cases the drying was performed only on the vapor.

To determine the boiling point the tip of the long tube was dipped under previously boiled mercury and then broken while the depth of the open tube was noted. The liquid was distilled by heating in an oil bath the flask containing it, while the other flask was cooled in water or ice. Then when enough of the liquid was collected in the previously empty flask which formed part of the apparatus, the second flask was heated and the first one cooled. The heating of the oil bath was conducted very slowly so as to allow the liquid to attain the full temperature of the oil. When this approached the boiling point, the heating was slowed down still more.

Experiments on Density and Melting Point

Details of the various experiments are given which we omit for lack of space. We should note, however, that with such a profound change as seemed to take place in these liquids on drying a marked change in density would also be observed. But benzene, carbon tetrachloride, carbon bisulphide, ether, bromine, sulphur dioxide and nitrogen trioxide were each left standing for a year and closed with phosphoric oxide, and the volumes remained the same, although a change of one part in ten thousand would have been easily detected.

Supplementary experiments were made in regard to melting points as follows: A tube containing sulphur which had been purified for atomic weight purposes was set up in 1913 and its melting point was 112.5 deg. The same reading was obtained in 1914, but by 1922 the melting point had become 117.5 deg. Professor Smits of Amsterdam points out that this is a confirmation of his recent theory of allotropy. A sample of iodine, also purified for atomic weight purposes, showed a change from 114 deg. in 1913 to 116 deg. in 1916 after similar

drying in the interval. Experiments are in progress for determining the specific heat of the dried liquids and the density of their vapors.

Professor Armstrong's enthusiasm will now become apparent. The amount of water removed by this long drying is so slight as to be apparently negligible; and yet the results support the hypothesis that at all events in the liquids tested we have aggregations of molecules probably held together by their external fields of force and that in the presence of the very slightest amount of water these aggregates separate or are loosened up. It seems to indicate the presence of colloidal phenomena clear outside the domain of colloid chemistry, to lend a shade of color to the contention that colloid chemistry is universal or, if we would follow Dr. Loeb or Professor Armstrong, that there isn't any such thing and that it is all just plain chemistry. It adds to our knowledge of the amazing qualities of water as a solvent and it carries us a step nearer toward the light in a direction where more light is sorely needed, and that is in the study of what a liquid really is. It is easy enough to visualize the molecules of a gas bumping around like so many balloons, but in a fluid the imagination of familiar things is less helpful. It begins to seem as though there were something like liquid crystals formed of aggregates of molecules and that the presence of water absorbed or took over the forces that hold them together. It may be that the alcohol molecules, for instance, have a definite geometric shape as suggested by the Lewis-Langmuir theory, and their external fields of force, being the same for each molecule of the same substance, cause them to interlock into the prescribed forms we know as crystals. Then when there is but one molecule of water with its own peculiar and different shape among many thousand molecules of alcohol, the interlocking of the alcohol molecules is prevented. It would be like inserting a block that "doesn't belong" into a picture puzzle. And why does the temperature of the vapor of the dry liquid prove to be only 2 deg. above normal, when taken at 3 cm. above the surface or at its dew point? This note has induced some eminent physicists to declare that for this reason there must be some mistake. But it may be right after all. There may be a time factor in this bunching or aggregation of the liquid molecules, although this is short, for as soon as the condensed liquid gets back to the mass it does not boil until the high degree of heat is reached. The precautions taken make it unlikely that the higher boiling points are due to the presence of any phosphorus compounds.

In fact the whole subject is causing a great deal of dispute in chemical circles in London.

Legal Notes

By Wellington Gustin

Tucker Decentralized Control System for Roasting Furnaces Not Invention

In a suit brought by the New Jersey Zinc Co. against the American Zinc, Lead & Smelting Co. in the United States District Court of Maine, the validity of patent 931,815, issued Aug. 24, 1909, to Allen Tucker of Mineral Point, Wis., was put in question.

The Tucker patent in suit involved certain improvements relating to an ore-roasting furnace generally known as the Hegeler furnace, invented by Edward C. Hegeler under patent 303,571, issued Aug. 12, 1884. In this furnace the ore is progressively moved forward on the hearths by rakes which are pulled through the hearths by the rake-moving machinery located at each end of the furnace. Now the Jersey Zinc Co., as plaintiff, says that prior to the invention of the Tucker patent, which it owned, two men were required at each end of the furnace for the raking operation. One man, called the "machine man" or "floor man," concentrated his attention wholly upon the operation of the mechanism or machinery for mechanically moving the rakes. Everything that had movement or which controlled selection or direction was in the hands of that man. He manipulated the control devices from the ground or floor adjacent to the head frame of the rake reciprocating mechanism. The other man, called the "hooker" or "platform man," attended to the hooking and unhooking of the rakes and the guiding of the rods and rakes into the hearths. Since his operating station was at various heights or levels, platforms were provided at each end of the furnace and on each side thereof, upon which the hooker stood in the performance of his duties.

Tucker decentralized the control by placing motor control devices upon each of the seven platforms so that the hooker could operate the mechanism in addition to his regular duties, thus eliminating the floor man.

The question the court asks is, Did Tucker make a patentable invention when he ran the control lines to the platforms instead of running them to the floor? The only substantial thing which he contributed or sought to contribute to the art was the convenience and economy obtained by reducing the number of men necessary to operate the kiln.

Simplicity Not Argument Against Invention

However, the court says, the simplicity of a device covered by the patent is not an argument against invention. When a thing has succeeded it is very likely to seem plain to any one. A classic quotation is here given.

"The very simplicity of an invention, which leads the inexperienced to infer little merit or application in the inventor, is most commonly the sequel of complications, which in succession have been contrived by him, and in succession been rejected. Indeed, who that ever cast a glance of intelligent observation upon our manufactures, or that has ever been struck with the combined simplicity and efficacy of the means employed, can do otherwise than infer that any one of the means that he admires must have been selected for superiority, when perhaps a thousand others have been rejected?"

Further, it is said that no test has been formulated by which a satisfactory line can be drawn between the products of the inventor's intuition and the results of the mechanic's skill, but that question must be left to a careful exercise of the judgment, guided by the established rules of the law.

Finally, however, the court held that the Tucker patent, for improvements in an ore-roasting furnace which consisted only in lengthening the handles of the controls for certain machinery so that they all could be operated by one man instead of requiring two as heretofore, did not disclose invention and was invalid.

Electrical Characteristics Of Dry Cells—I*

By G. W. Vinal and L. M. Ritchie

Showing the Effect of Temperature on Voltage, Amperage, Shelf-Life, and Tests of Dry Cells—Tables and Curves of Discharge at Constant Resistance and Constant Current Show Capacities to Different End Points at Different Rates

THE Bureau of Standards recently called a conference of leading manufacturers, various government departments and a few of the largest individual users of dry cells to consider the standardization of sizes of dry cells and flashlight batteries, and the revision of the specifications for them. This conference met on Dec. 5, 1921. An abstract of the work of the conference was published in this journal.[1] The sizes of dry cells and flashlight batteries which were adopted as standard are shown in Fig. 1. The data in this paper relate particularly to dry cells of the ordinary size, 2½x6 in.

Effects of Temperature on Dry Cells

Effect of Temperature on Voltage

The effect of temperature on the open circuit voltage of dry cells is small and for most purposes can be neglected entirely. The temperature coefficient is

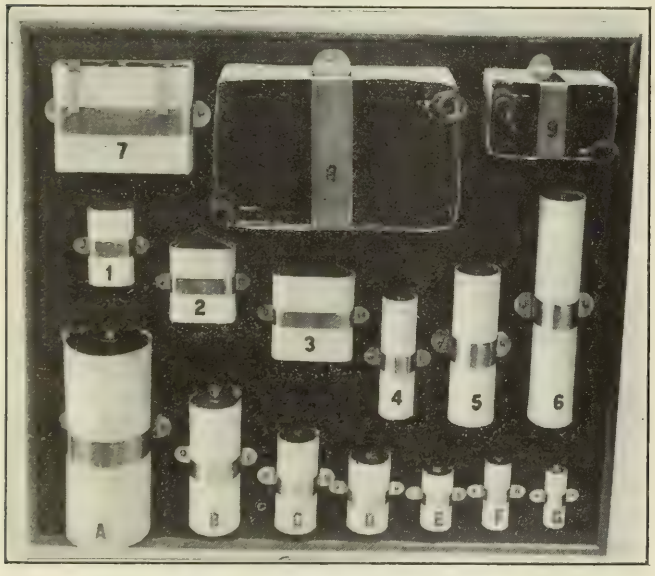

FIG. 1—SIZES OF DRY CELLS AND FLASHLIGHT BATTERIES ADOPTED AS STANDARDS

positive within the ordinary range of temperature—that is, an increase in temperature is accompanied by a rise in voltage. Measurements carefully made on a number of dry cells of various brands and even on different cells of the same brand are not very concordant. Differences are also found between measurements made by a potentiometer and by an ordinary voltmeter, the temperature coefficient appearing to be greater in the latter case. In Fig. 2 is given a curve that represents the average of sixteen different cells, including four different brands measured at the Bureau of Standards. These cells were all of the No. 6 size and of the paper-lined construction. They were kept at a fixed temperature for at least 24 hours before being measured by a voltmeter having 100 ohms per volt of its scale. The voltmeter measurements are given because they are of the greatest practical use. The effect of extreme low temperatures on the voltage of dry cells is given in Scientific Paper 434 of the Bureau of Standards.

Effect of Temperature on Short-Circuit Current

Between 0 and 25 deg. C. (32 and 77 deg. F.) the short-circuit current increases approximately 1 amp. for each 3 deg. C. (5.5 deg. F.) rise in temperature.

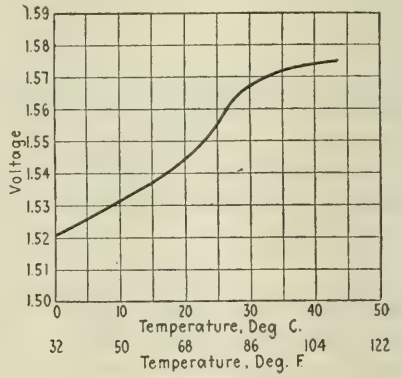

FIG. 2—EFFECT OF TEMPERATURE ON OPEN CIRCUIT VOLTAGE OF DRY CELLS

Mean of measurements on sixteen cells, No. 6 size, of the paper-lined construction, including four different brands. All cells kept at fixed temperatures 24 hours before being measured.

At higher temperatures the rate of increase is somewhat less. The curve of Fig. 3 shows the relation of the short-circuit current to temperature for a group of six cells of the paper-lined construction measured at the Bureau of Standards. Each point plotted is the

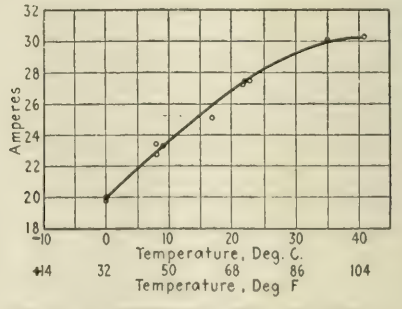

FIG. 3—EFFECT OF TEMPERATURE ON SHORT-CIRCUIT CURRENT

Mean values for a group of six cells maintained at each of the temperatures indicated for at least 24 hours prior to the measurement.

*This paper is taken from Chap. IV of the forthcoming circular 79 of the Bureau of Standards on Electrical Characteristics and Testing of Dry Cells. Published by permission of the Director of the Bureau.

[1]Vol. 26, p. 178, Jan. 25, 1922.

mean value of the six cells after they have been kept at the temperature indicated for at least 24 hours. The temperatures were taken in the following order, 22, 0, 22.5, 8, 0, 21.8, 35, 41, 8, 16.8 and 9 deg. C. This shows that the shape of the curve is well defined and that the short-circuit current reading at any temperature can be repeated with fair accuracy when the temperature of the cell is brought back to the same value.

Effects of Temperature on Storage

Heat produces deterioration of dry cells in two ways. First, it tends to produce leakage; this may be observed when the sticky electrolyte has oozed out around the seal of the cell. Second, it increases the rate of the chemical reactions taking place within the cell. The deterioration of the cells is usually measured by the decrease in the short-circuit current with time when the cells are stored on open circuit. This is not a true criterion of the decrease in service capacity of the cells, but is a convenient method of estimating the depreciation. In Table I is given the percentage decrease

TABLE I—EFFECT OF TEMPERATURE ON THE SHORT-CIRCUIT CURRENT OF DRY CELLS STORED ON OPEN CIRCUIT

Temperature of Storage	Percentage Decrease in Short-Circuit Current at End of 10 Weeks
5° C. (41° F.)	4
25° C. (77° F.)	10
35° C. (95° F.)	19
45° C. (113° F.)	25
55° C. (131° F.)	52
65° C. (149° F.)	71
75° C. (167° F.)	98

in short-circuit current at the end of 10 weeks for cells stored at various temperatures. The figures have been taken from an article by Pritz.[2] Recent experiments show that the measurements of Pritz for cells stored at 25 deg. C. are approximately correct for dry cells when new, but the rate of decrease of short-circuit current becomes less as the age of the cell increases, the total decrease during a year at room temperature being about 25 per cent. The table shows that it is necessary to keep the cells as cool as possible while they are in storage or being shipped. Temperatures of 55 deg. C. or above are not likely to be reached under any ordinary conditions of storage.

Effect of Temperature on Service Capacity

For heavy service a moderately high temperature is desirable, but for light service a low temperature is better. The data of Table II are taken from Pritz,[3] showing the hours of continuous service from cells of one manufacturer when discharged through various resistances until the closed-circuit voltage had fallen to 0.5 volt. The cells used for these measurements were the 6.5x15 cm. (2½x6 in.) size. Exactly the same figures for the 2-ohm test were also given by Ordway.[4]

Table II shows that 50 deg. C. (122 deg. F.) is the most favorable temperature when the external resistance is 8 ohms or less. However, a word of caution is necessary in applying this table to actual use. This is a continuous test, while cells are used ordinarily only part of the time. Hence the heat that may seem to make the cell more efficient in some cases may also cause so much deterioration during the idle periods as to be disadvantageous. For example, Table II shows 160 hours' service at 50 deg. C. when discharging

TABLE II—HOURS OF SERVICE OF DRY CELLS DISCHARGED TO 0.5 VOLT AT VARIOUS RATES AND TEMPERATURES

Temperature	Resistance of External Circuit in Ohms 2	4	8	16
0° C.(32° F.)	40	80	270	560
25° C.(77° F.)	60	94	260	700
50° C.(122° F.)	70	160	250	650
75° C.(167° F.)	65	158	315	615

TABLE III—HOURS OF SERVICE OF DRY CELLS, NO. 6 SIZE, DISCHARGED TO 0.6 VOLT AT FIXED RATES OF CURRENT AND AT VARIOUS TEMPERATURES

(Average of results of tests made on 3 standard makes of dry cells of paper-lined construction.)

Temperature	Service at Various Rates of Discharge in Amperes 0.1 Hours	0.25 Hours	0.50 Hours	0.75 Hours	1.00 Hours
0° C.(32° F.)	136	40	14	7	5
25° C.(77° F.)	220	64	24	13	9
30° C.(104° F.)	300	94	31	18	11

through 4 ohms; but this is less than 7 days. Table I shows that at this temperature the deterioration of the cell as measured by the short-circuit current is about 4 per cent per week on the average. If the cells were to be used over a period of several weeks, the hours of actual service obtainable would be much less than those shown in Table II. The obvious remedy is to keep the temperature lower.

The data given in Table II apply to cells discharging through a fixed resistance. It is also of importance to have data for cells discharging at a fixed rate of current. Results of tests recently made at the Bureau of Standards are given in Table III. The temperatures were kept constant by thermostatic control and the current in each case was maintained at the fixed value day and night throughout the test.

Capacity of Dry Cells

Since dry cells are mostly used on circuits of which the resistance is constant or nearly so, the capacity is usually expressed as the number of hours or days that the cell will continue to give service on such a circuit. This period is calculated to the time that the terminal voltage has fallen to some arbitrary value below which the service is not satisfactory. For example, the cut-off voltage of a group of three coils for telephone service is 2.8 volts. Such service is intermittent and extends over a number of months. The capacity of dry cells may also be expressed in terms of ampere-hours and watt-hours, but to obtain these data it is necessary to integrate carefully measured discharge curves. In any case the capacity, whether expressed as hours, ampere-hours or watt-hours, depends on the condition of the cells, the way they are made and the arbitrary choice of the cut-off voltage. In the pages that follow the most reliable data for the capacity of standard makes of No. 6 paper-lined cells discharging through fixed resistances and at constant current rates are given.

Table V shows clearly the gain in hours of service that is to be obtained by making the current drain light. For the cut-off voltage of 1.2 volts discharging through 2 ohms, 2.2 hours was obtained, but through 8 ohms the cell gave twenty times the service and through 64 ohms, 480 times the service.

Table V shows that when the voltage has fallen to one-half its initial value the cell is by no means one-half discharged. The true measure of discharge of the cell is the ratio of the energy delivered to the total energy contained, and this must be measured in watt-hours.

Just as the voltage is not a criterion of the service capacity remaining in the cell, so also the short-circuit current is not a true measure of the cell's capacity.

* Estimated by exterpolation.

Excessively large short-circuit currents when the cell is new do not indicate that such cells will give more service than others yielding average currents. These excessive currents which are sometimes produced for advertising purposes may be the result of harmful additions to the usual ingredients of the cell. With any given brand of cell, a test that shows, for example, a decrease of 40 per cent in the short-circuit current does not mean that 60 per cent of its service capacity remains.

Discharge Through Constant Resistances[5]

Initial Working Voltage.—It is important to know what working voltage can be expected from the cell at the beginning of its service life under various discharge conditions. This of course is lower than the initial open circuit e.m.f. of the cell because of what is usually assumed to be the internal resistance of the cell. It varies with the current being drawn from the cell or with the resistance of the external circuit according to the figures in Table IV.

With circuits of greater than 1 ohm the initial working voltage is but slightly lower than the open circuit e.m.f. The difference between open and closed circuit voltage is not readily calculated from the value for the internal resistance of the cell because the latter is not a constant quantity since it varies with the current being drawn from the cell, from about 0.04 ohm at heavy drains up to several ohms at light drains.

Continuous Discharges.—In the first section of Table V will be found the life in hours to various cut-off voltages for cells discharged through various resistances.

A number of curves have been drawn based on the figures in Table V from which the characteristics of the cell can be studied more readily than from the table of figures.

If the cell discharged at the same efficiency through all resistances, a cell giving 100 hours through 10 ohms, at the same service efficiency should give 10 hours through 1 ohm and 1,000 hours through 100 ohms, etc. The efficiency, however, rises more rapidly for increasing resistances up to the region of 60 to 100 ohms, above which the rise is lower than for equal efficiency. It follows, therefore, that up to this region the efficiency is increasing, and above it decreasing. There-

[5]The subsections headed "Discharge Through Constant Resistances" and "Constant Current Discharge" are chiefly from a paper by C. A. Gillingham, *Trans. Am. Electrochem. Soc.*, vol. 34, p. 297 (1918), by permission.

Note.—Figures in parentheses are interpolated.

fre, the maximum efficiency lies in the vicinity of 60 t 100 ohms depending on the cut-off voltage.

Fig. 4 shows the continuous discharge results of the fst section of Table V plotted in terms of hours per ohm ordinate and a logarithmic scale to the base 2 of ohms for the abscissa. By this method it is possible put all of the results on the same plot without crowding the curves together in the region where there is e most occasion to use them. The actual hours of scharge are readily calculated from the hours per ohm the following relations:

ours of discharge = hours per ohm × ohms in discharge resistance.

his plot shows the following characteristics of continuous dry cell discharges:

(*a*) For any cut-off voltage the efficiency rises to a aximum as the resistance of the discharge circuit increases and then falls off rather abruptly.

(*b*) An increase in cut-off voltage causes this aximum point to move to the right.

The reason for the increasing efficiency as the resistance becomes greater (and hence the service lighter) no doubt due to the increasing completeness of the polarization. It becomes practically complete at 64 ms.

The falling off in efficiency for services lighter than at equivalent to a discharge through 64 ohms is cause of the local action within the cell, which is ten referred to as the shelf-life deterioration.

Local action consumes the zinc can and the other constituents as well as the useful service which the cell nders, so that as the period of discharge is increased ere is a relatively smaller amount of these available r service reactions.

It will be apparent also from examination of Fig. 4 at the shape of discharge curve for low resistances ust be quite different from that for high resistances. he relative distances between the various cut-off voltges show this.

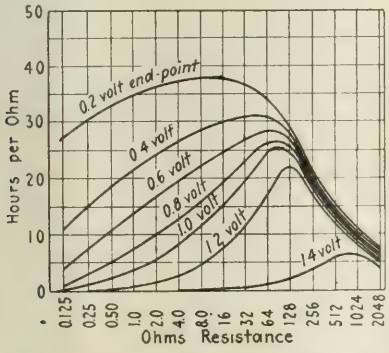

FIG. 4 — SERVICE EFFICIENCY CURVES FOR CONTINUOUS DISCHARGES THROUGH VARIOUS RESISTANCES

Intermittent Discharge.—The results of the various ntermittent tests are shown in Table V, from the econd division down. It will be noted that the first ve of these together with the continuous division form series of various length discharges in hourly cycles as ollows:

60 minutes per hour (continuous)
30 minutes per hour
15 minutes per hour
5 minutes per hour
2 minutes per hour
½ minute per hour

In Fig. 5 are shown the efficiency curves to the 0.8 volt end point for the various periods of hourly discharge. The maximum efficiency points move to the left toward the lower resistances as the period of discharge becomes lower, just as in Fig. 4 they move to the left as the cut-off voltage is lowered. The latter is true regarding the cut-off voltage for any given period of discharge less than 60 minutes, just as it is for the continuous tests.

This leads us to a consideration of what is called "severity of service." Severity of service decreases with increased resistance and decreased period of closure. In other words, severity of service is analogous to average rate of output. Two cells would be working at the same average rate of output if, for instance, one discharged at 1 amp. continuously and the other at 10

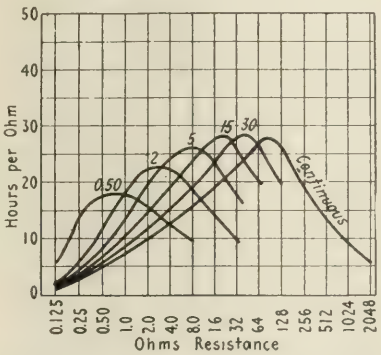

FIG. 5 — SERVICE EFFICIENCY CURVES TO THE 0.8 VOLT END POINT FOR VARIOUS PERIODS OF DISCHARGE
Numbers on curves refer to minutes of discharge per hour.

amp. for one-tenth of an hour each hour. Each would deliver 1 amp.-hr. per hour. "Severity of service" may be defined as equal to the percentage of the total time during which the cell is actually discharging, divided by the resistance of the circuit. When the severity of service is low, all the discharge curves for various rates coincide if the hours of service are plotted against the severity of the service to any given cut-off voltage. In other words, the efficiency and shape of the curve are approximately the same for the same severity of service whether the discharge is continuous or intermittent. This applies to service through a resistance of 16 ohms or more.

Thus far all conclusions regarding the intermittent characteristics are based upon the series in which one cycle occurs every hour, the period of discharge varying between ½ and 60 minutes. In order to ascertain the effect of cycles longer and shorter than 1 hour, tests were made as follows:

5 minutes every	10 minutes
30 minutes every	6 hours
5 minutes every	6 hours

The figures for these tests are shown in the 7th, 8th and 9th divisions of Table V.

Tests run 5 minutes every 10 minutes are discharging the same percentage of the total time as those run 30 minutes per hour. By comparing the results for these two tests (divisions 2 and 7 of Table V), it will be found that the two are identical (within the limit of error), except in the very low resistances, where a considerable difference is found, particularly at the higher cut-off voltages. The results are of course lower

for the longer 30-minute discharge period than for the shorter 5-minute period. The same will appear by a comparison of the 30 minutes every 6 hours with the 5 minute per hour tests (divisions 4 and 8, Table V). Appreciable discrepancies occur only when the resistance is below 1 ohm. In most cases, therefore, it may be assumed that any discharge cycle will give the same results as the 1-hr. cycle with the discharge covering

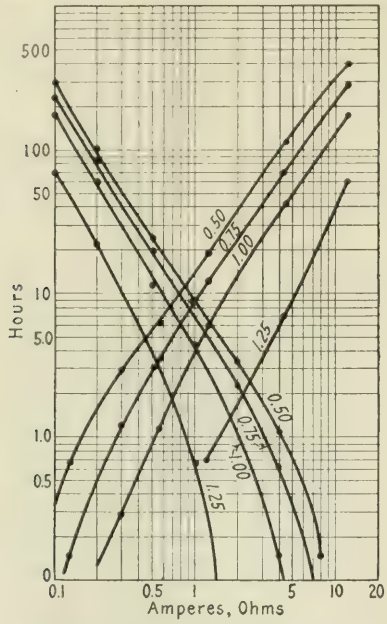

FIG. 6—CONSTANT CURRENT AND CONSTANT RESISTANCE DISCHARGE. 25 DEG. C.

the same proportion of the time. This statement, of course, must be applied with discretion especially in cases of discharge periods of considerable length and moderate resistances.

Constant Current Discharge

In Table VI are shown the results of a number of tests in which the resistance of the circuit was varied as the cell ran down so that the current drain remained constant in value throughout the test. In the constant resistance discharges, of course, the current drain decreases in direct proportion as the working voltage of

TABLE VI—HOURS OF CONTINUOUS CONSTANT CURRENT DISCHARGE

Cut-off Voltage	Amperes 8	4	2	1	0.5	0.2	0.1
1.2	.....	0.015	0.12	0.7	4.0	20	78
1.0	.....	0.24	0.82	3.6	13.5	49	140
0.8	0.047	0.43	1.9	6.3	21.0	66	183
0.6	0.137	0.82	3.1	9.2	27.5	80	220
0.4	0.240	1.29	4.3	12.0	36.0	92	237

the cell decreases. The cell, therefore, delivers current at a slower and slower rate as it becomes exhausted. In the constant current test, however, the cell is forced to deliver current at the same rate when nearly exhausted as at the beginning of the test. It is therefore to be expected that the discharge curve will drop less rapidly at the beginning and more rapidly at the end than for a constant resistance test of about the same average drain.

Comparison of Discharge Through Constant Resistances With Discharges at Constant Current

Dry cells have been commonly used on circuits of which the resistance is constant, such as telephone, ignition and bell circuits. There is now a growing tendency to use them also as a source of power for the operation of radio and other apparatus for which a constant current is necessary. The duration of the discharges of both kinds to various cut-off voltages are given in Tables V and VI (Gillingham's measurements) and also in Figs. 6 and 7, which are plotted from results obtained at the Bureau of Standards. Different brands of cells were used in making these experiments and the temperature also differed by several degrees. It is not surprising, therefore, that there are slight differences in the results, but the general agreement indicates that the performance of paper-lined cells of standard make is reasonably uniform and consistent. The curves which are given apply to continuous discharges at constant current and through constant resistances.

In order to determine the constant current at which a cell must discharge to give comparable service to that which it can give on a constant resistance circuit, Figs. 6 and 7 may be used. The former applies to the paper-lined cells and the latter to a bag-type cell of American manufacture. In either figure the curves sloping downward to the right are for the discharge at constant current for which the abscissas are amperes. The curves sloping downward to the left are for discharges through constant resistances. For these the abscissas are ohms. Example: To determine the constant current which will give the same service to 0.75 volt as for the cell discharging through 5 ohms. Starting at the 5 ohm point at bottom of diagram, follow the line vertically upward to its intersection with the curve marked 0.75 and then follow the ordinate horizontally to the left to it

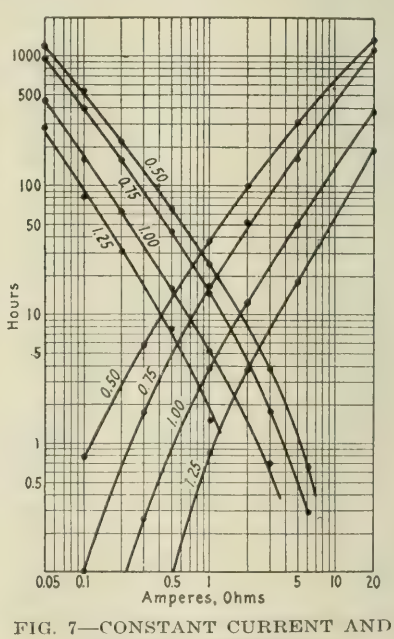

FIG. 7—CONSTANT CURRENT AND CONSTANT RESISTANCE DISCHARGE. 25 DEG. C.

intersection with the other curve marked 0.75. From this intersection follow line vertically downward to scale of amperes at the bottom of the diagram. On Fig. 6 this is found to be 0.19 amp.

Ampere-Hour Capacity

The ampere-hour capacity of dry cells does not possess the theoretical interest or practical value which the ampere-hour capacity has for storage cells, but it is occasionally necessary to determine it. This may be

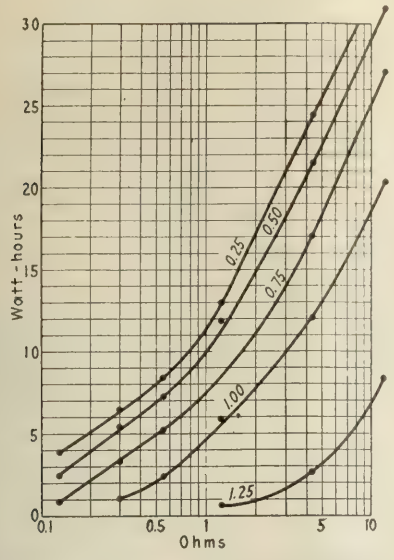

FIG. 8—WATT-HOUR CAPACITY. CONSTANT RESISTANCE DISCHARGE. 25 DEG. C.

ne for continuous discharges with the aid of Figs. 6 d 7.

When the cells are discharged at a constant current te, the capacity in ampere-hours to any specified cut- voltage can be calculated immediately. It is the oduct of the current by the duration of the discharge. us in Fig. 6 the ampere-hours for a cell discharging a fixed rate of 0.5 amp. to 0.75 volt is found to be

$$0.5 \times 19 = 9.5 \text{ amp.-hr.}$$

The more usual case, however, is for the cell to be scharged through a fixed resistance, the current deasing as the discharge progresses, because of the lling voltage of the cell. The equivalent constant curnt may be estimated for the discharge through any lue of resistance shown in either Fig. 6 or 7 as deribed in the preceding section and from this the apoximate equivalent in ampere-hours computed. An ample was given in which the constant current equivent to a discharge through 5 ohms to an end point 0.75 volt was found to be 0.19 amp. The time of the scharge was 85 hours. The ampere-hours were

$$0.19 \times 85 = 16 \text{ amp.-hr.}$$

The most exact way of computing the ampere-hours to determine the current flowing at a number of riods during the discharge of the cell by dividing the rminal voltage of the cell at such times by the fixed sistance of the circuit. From these values a plot can made and the average value of the current during e discharge obtained by integrating the curve with a animeter.

It should be remembered that the performance of fferent brands of cells differs considerably and that ie age and temperature conditions also have a marked fluence. The performance of typical brands of cells ven in Figs. 6 and 7 serve only as a rough indication the period of service and ampere-hour capacity that ay be expected under other conditions.

Watt-Hour Capacity

The watt-hour capacity is of greater interest than ie ampere-hour capacity, because it represents the tual energy that can be derived from the cell. It is ot computed as easily as the ampere-hour capacity, ecause of the necessity of determining the average voltage, which changes throughout the period of discharge.

If the discharge is made at constant current, the average voltage is most simply obtained by plotting the voltage readings and integrating the curve by a planimeter. In this case the watt-hour capacity is the product of the average voltage by the fixed value of current and by the period of discharge to any predetermined cut-off voltage.

If the discharge is made through a fixed resistance, both the current and the voltage vary throughout the discharge. It is then necessary to plot a curve of the voltage squared for integration. The watt-hour capacity is determined as the product of the average value

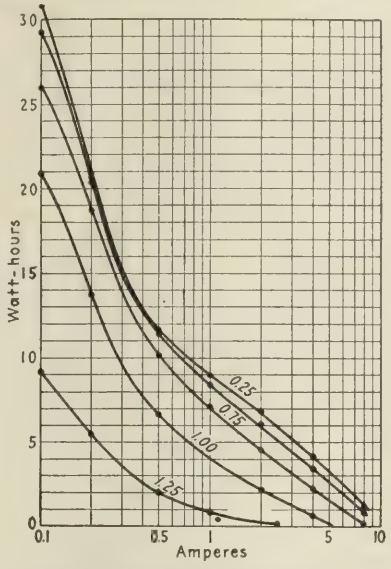

FIG. 9—WATT-HOUR CAPACITY. CONSTANT RESISTANCE DISCHARGE. 25 DEG. C.

of the voltage squared multiplied by the time of the discharge and divided by the fixed value of the resistance.

Since the watt-hour capacity of the cells cannot be computed from any of the preceding data, curves of Figs. 8 and 9 are given for continuous discharges of the ordinary paper-lined cells of No. 6 size discharging through fixed resistances and at constant current to the cut-off voltages indicated on the individual curves.

Part II will appear in a subsequent issue.

Failure of Paint and Varnish on Exposure to Weather

During the recent meeting of the American Society for Testing Materials at Atlantic City there was an extended informal discussion of the mechanism of failure of paint and varnish films on exposure to the weather. One party to the discussion claimed that a paint or varnish film should contain moisture in order to retain its elasticity. The known beneficial effect of baking a varnish film was then cited as being contradictory to this theory that moisture improved the durability of paint or varnish. The importance of the problem makes it appear advisable to study baked varnish films in order to obtain some definite data on the effect of baking. The Bureau of Standards has commenced an investigation in which a series of spar varnishes of varying strengths of oils will be baked on tin panels at different temperatures, and then tested for durability when exposed to the weather.

Application of Electric Service To the Chemical Industry

Power an Important Part of Manufacturing Cost—Electric Power Is Applied for Motor Drives, Illumination, Heating, Transportation, Electrolysis and Electrical Precipitation—Some Points to Be Observed

By William B. Todd
Engineering Department, E. I. du Pont de Nemours & Co.

POWER forms a large percentage of manufacturing cost in many chemical industries. But how many plant managers are familiar with the many applications of power? To the average manufacturer steam generation, transmission and use in chemical processes are more or less understood. Electricity, however, with its increasing uses, is little understood; and in many cases advantage is not taken of applications that would prove of value.

The applications of electrical service to the chemical industry may be roughly grouped under the following headings:

Motor drives	Electrolysis
Illumination	Electrical precipitation
Heating	Miscellaneous uses
Transportation	

Consideration of these headings will be briefly discussed. There are chemical plants now using all of these applications.

Motor Drives

Except in electrochemical plants, the largest percentage of a plant's electrical consumption is used in motor drives. Pumps, compressors, mixers, grinders, agitators, beaters, centrifuges, rotary driers, continuous filter presses, nitrators, etc., are all driven efficiently by electric motors if proper applications have been made. By proper motor application is meant the strict attention to correct type, correct size and correct installation.

Before selection of the correct type it will be necessary to consider the two classes of electric motors—direct current and alternating current. Except in older plants it will be found that alternating current is in general use on account of the advantages this system offers in the reduction of transmission losses and line costs, due to the ability to transform to higher voltages and consequent lower current and the use of smaller wire sizes.

Electrical service may be generated or purchased. The electric utility companies as a rule furnish only alternating-current service and the majority of chemical plants generating their own power use the alternating-current system. The problem of generation or purchase of electrical service will not be discussed here, as we are dealing with its application. The cycle of plant operations, however, must be so arranged that unusual peaks will not obtain, the penalty being increased costs due to the "demand charge" if power is purchased and investment in increased generating capacity if generated.

Use of Alternating-Current Motors

With alternating-current systems we are confronted with the power factor condition. The power factor in most industrial plants is "lagging" and represents the current doing real work in electrical machinery compared to that doing real work plus the amount doing "wattless" or unnecessary heating work in the coils of that machinery. The effect of lower power factor is the reduction of the output of generators, transformers and distributing feeders; and the impairing of voltage regulation. Low power factor is caused by underloaded induction motors and can be remedied by application of motors of correct rating or by the installation of synchronous motors on such large loads as continuously operated pumps or air compressors, or by the use of static condensers.

These last two items of electrical equipment cause "leading" current in the lines and will neutralize the lagging power factor caused by underloaded induction motors. Correction of power factor will save investment in added plant generating capacity.

It is generally conceded that alternating-current motors are more reliable and, in the case of the chemical industry, safer than direct-current motors, due to absence of commutators and their attending trouble. Direct-current motors are designed for 110-, 220-, 550-volt service, while alternating-current motors may be designed for various voltages, phases and frequencies, but the specifications in most general use are 110, 220, 440, 550 or 2,200 volts, two- or three-phase (single phase for fractional horsepower motors) and twenty-five or sixty cycles. The direct-current motors are divided into three types—series, shunt and compound. The alternating-current motors in industrial use are the squirrel-cage induction motor, the slip-ring induction motor and the synchronous motor.

Correct Application of Motors

For correct application to various loads the following table will roughly cover the type of motor to be used:

Nature of Load		Direct Current Motor	Alternating Current Motor
Speed	Starting Torque		
Constant...	Low.....	Shunt	Squirrel-cage or synchronous
Constant...	High.....	Compound or series.	Slip-ring
Variable...	Low.....	Shunt or compound.	Slip-ring
Variable...	High.....	Compound	Slip-ring

Synchronous motors, due to their higher cost and necessity of direct current for their fields, are seldom used in industrial plants except in large sizes to improve power factor conditions as has been explained before. Slip-ring motors are not efficient at speeds under synchronous speed rating, but afford the only practical method of obtaining variable speeds with alternating current motors. The nature of the load to be driven should thus be carefully considered before selecting the proper type of motor.

Choosing the Correct Size of Motor

One of the greatest faults in the application of motors has been that of "over-motoring" or installing motors of too large capacity. This fault has been caused by the desire to play safe; but, due to it, there are today many plants operating motors at greatly reduced efficiencies and power factor, and consequent higher power costs, as the maximum efficiency and

wer factor of a motor is at rated load. Whether dividual or group drive of machinery is used, careful sts should be made to obtain the average and maxi- um loads, and the proper size motor installed.

Motor ratings are based on the maximum continu- s temperature at which the heat caused by the passage current through the windings will be dissipated at e same rate as generated. Commercial motors are w manufactured with 40 deg. C. and 50 deg. C. rat- gs, expressing the permissible temperature rise above ambient temperature of 20 deg. C.—at rated capac- y. The 40 deg. motors permit of an overload of pproximately 25 per cent above normal rating, while) deg. motors permit of no overload. Naturally the) deg. motors are cheaper and in purchasing motors e difference in ratings should be taken into considera- on.

Correct Installation of Motors

Correct installation is particularly important in chem- al manufacturing buildings. It is well worth the gher installation cost to use 30 per cent para rubber sulation for conductors and to run the conductors in etal conduit, lead cable or in grooved timbers. This tter installation is fairly expensive; but, where metal nduit would be eaten through in a few weeks, the rooved timber and asphaltum-like compound will com- ine to give good service. The timbers are run through ie entire length of the building and the connections to ie circuits made on the exterior of the building. Lead able, while more satisfactory in withstanding acid imes than metal conduit, requires considerable lead urning; and, due to the mechanical injury that it is kely to receive, acid will leak into the wiring. Safety witches, overload relay and no-voltage release coils on arting apparatus and the installation of all electrical quipment from a safety standpoint are all-important.

In acid buildings it is often advisable to make up oil- witch boxes containing a lead reservoir filled with ransformer oil, so that the fuse blocks and all of the nife switch but the handle are submerged in oil. Iotors are frequently installed in motor houses outside f the manufacturing building and the power trans- itted to the machinery in the building either by a belt arried through a duct or by a shaft containing a pulley n the motor room. Remote control of motors from ush-button stations offers operators a convenient ethod of starting and stopping their machines and in uildings where there are dangerous operations the nstallation of these push-button stations at different oints is a step toward safety of operation. In the xplosives end of the chemical industry it is frequently dvisable to start and stop the operation of machinery t some distance from the building and the push-button tations are mounted on posts at a proper distance from ie operation.

Protection of Motors From Fumes

For protection of motor windings against acid and ther chemical fumes it has been found necessary to oat them with a solution of flexible black enamel and exible compound and bake from 40 to 60 hours at 75 eg. F. (36 deg. C.). The motor is then removed from ie oven and while still hot it is suspended by a sling o that the protruding windings can be lowered into a arge flat pan containing compound similar to asphalt, ut having a much higher melting temperature.

Motors receiving this treatment will withstand ex- osure to fumes that would put factory-impregnated motors out of business in a very short time. This protection, however, will gradually break down due to contraction, expansion and vibration of the stator laminations. A "dope" gang is therefore employed to prevent this breakdown. This gang neutralizes the acid deposits on the motors by swabbing with a solution of soda ash and alcohol, wirebrushing and sandpapering the metal parts and coating the winding with Harrison's quick-drying asphaltum paint applied with a paint "gun." The paint gun operates somewhat on the principle of a blow torch, the pressure being applied either by the plant air line or a tire pump. The "gun" is superior to a brush in applying the paint into every recess where fumes can enter.

The more important advantages of electric motor drives are:

1. Direct application of power where desired.
2. Minimizing of shafting and belting to give better illumination and handling of material.
3. Constant speed, causing increase of production.
4. Reliability, as breakdowns are usually confined to a single machine.

Illumination

Proper illumination has increased production in many industries, particularly in shops where hand and accurate machine work predominate. In the chemical industry the operations consist mainly of tending machines, and, as a general rule, the lighting system should consist of general direct lighting, an average of 1 to 1.25 watts per sq.ft., with local lighting at sight glasses, peep-holes, gages and places where greater intensity is desired.

The chief problem in interior illumination is to avoid fatigue and injury to the eyes of the operators by reduction or elimination of glare. This is accomplished by properly shaped reflectors and frosting of lamps. Indirect lighting does not, as a rule, lend itself to chemical operations due to the style of construction of chemical factory buildings. On account of fumes from most operations it is advisable to use vapor-proof globes. Where the explosive risk exists it is advisable to illuminate the interior by means of lamps inclosed in tilted glass front boxes mounted on the walls, the backs of the boxes permitting opening from the exterior of the building, and the circuits being run open on knobs on the exterior of the building to permit easy inspection. The outside type of reflector installed outside on posts opposite windows affords illumination for the interior of buildings with a high explosive risk.

It has been found advisable by safety authorities to restrict the use of nitrogen-filled Type "C" lamps in buildings of the chemical industry due to the high surface temperatures of these lamps. Lamp guards are advisable where there is a possibility of contact, particularly in the case of lamps at low heights. Drop-cord lighting should never be used where there is a vapor or dust risk. The installation of red lights over safety shower baths in acid buildings is very desirable. As many chemical operations are continuous, all passageways should be lighted and outside lighting carefully planned so that the operation of the plant on the night shift will be just as productive as on the day shift. In all places where possible the lamps and reflectors should be periodically cleaned to obtain maximum illumination from the energy that is being consumed.

Electric furnaces are used in the manufacture of certain chemical products, such as carbon bisulphide,

phosphorus, calcium carbide, calcium cyananide, etc., and in the fixation of atmospheric nitrogen.

Heating

A field of electric heating especially adaptable to the chemical industry is that to be obtained by the application of the electric resistance type of oven heaters such as are used by the automobile industry in enameling ovens. The application may be made directly, by the installation of the heaters in rotary driers, or below horizontal refining tanks; and indirectly, in oil heat transmission systems, by installing the heaters in a heating tank of high flash point oil which is circulated through the jacket of the still or autoclave. For operations requiring long heating periods this application does away with attendance of coal-, oil- or gas-fired furnaces to heat the oil. The advantage of electric heating is the automatic control of temperature by means of pyrometer-controlled magnetic switches. A kilowatt-hour of electrical energy is equal to 3,415 B.t.u.

Transportation

Due to the fact that the majority of chemical plants require numerous buildings, and in some cases safety spacing, transportation of raw, semi-finished and finished materials becomes an important consideration. Where roadways are adjacent to all manufacturing buildings, transportation may be taken care of by horses and wagons and gasoline or electric motor trucks. Where narrow-gage or tram tracks are installed, the motive power can again be furnished by horses and gasoline or electric locomotives. The following interesting data were secured from a chemical plant that has used all three forms of motive power.

1. Two electric locomotives did the same amount of work as fifteen horses. Including maintenance of horses and wage of drivers, the total cost of transportation per operating hour with the fifteen horses was $11.75. The total cost of transportation per operating hour with the two electric locomotives, including operators, repairs, charging and miscellaneous material, was $1.60. This latter charge did not include battery replacement, but assuming at least 2 years' life of battery, the cost would be increased to only $2.20 per hour.

2. Gasoline locomotives were out of running condition 50 per cent of the time and for the hours operated cost $1.50 per locomotive-hour. The electric locomotives had a "use factor" of practically 100 per cent and cost 74 cents per locomotive-hour. Neither of these figures includes operators' wages, which were the same in both cases and the available operating time per month averaged 200 hours.

Storage Batteries for Electric Locomotives

Special types of batteries are manufactured for electric locomotives. The battery should always be so mounted on the locomotive that the flat of the plate comes against the direction of motion. This assembly permits a cushioning effect of the electrolyte against the flat of the plates, and prevents displacement of plates or breakage of the rubber jars. The tray of discharged cells can be quickly lifted from the locomotive by a hand crane and replaced by a tray of charged cells.

When operating but one shift, and with only one battery charge per shift, the constant current method of battery charging can be used. But with three shifts, or several replacements per shift, it will reduce the time of charging and the consequent reduction in investment in batteries to use either the constant potential or modified constant potential methods. The two latter methods automatically control the charging rate and do away with the manual control of the charging current rate to prevent excess rise in temperature of electrolyte. Ampere-hour meters in conjunction with relays automatically cut out the battery when fully charged.

Electrolysis

Chemists as a rule are familiar with the application of direct current to electrolytic work. The electrolysis of saturated brine in concrete body cells containing graphite anodes, asbestos diaphragms and perforated sheet metal cathode plates produces chlorine gas in the anode compartment, and caustic soda liquor and hydrogen gas in the cathode compartment. Cells are connected in series and average from 3.2 volts to 4 volts per cell, depending upon the plugging of the diaphragm and the deterioration of the anodes. The energy efficiency of an electrolytic cell averages 55 to 60 per cent.

The decomposition of water to obtain oxygen and the byproduction of hydrogen is also accomplished by means of electrolytic cells. Except where water power is available the direct current is converted from alternating current by rotary converters of the booster type or by motor generator sets. Sufficient voltage range is necessary to handle the normal voltage variations of a series of cells.

Electrical Precipitation

The precipitation of dust, mist or fumes is accomplished in passing through vertical pipes by the ionization of the gases in the electrostatic field within the pipes. This electrostatic field is produced by means of wire or chain negative electrodes centered in the pipes, forming the positive electrode, the latter being grounded. A potential of 25,000 to 100,000 volts direct current is applied to the system. This high potential is secured by rectification of high potential alternating current with either mechanical disk-type commutator rectifiers or special two-electrode vacuum tubes. The ions travel with high velocity in a direction at right angles to the electrodes and impart a static charge to fume particles, causing them to be projected against the inner surface of the tubes, where they will either flow down the tubes or be rapped down. These installations have been successful in the recovery of nitric acid fumes, organic materials, potash from cement plants and the removal of sulphuric acid mist from gases from sulphur burners.

Miscellaneous Uses

Chemical laboratories have found many uses for electrical service in ovens, muffle furnaces, electrical settling, the starting of reactions by electrolysis and electrometric methods in chemical analysis. The mechanical department with an electric welding machine can cut down the cost of repairs, as equipment can be repaired without removal. With steel electrodes the bottoms of tanks can be repaired by welding while in place. The sterilization of water by ultra-violet rays has been accomplished.

Consideration of the applications of electrical service which have been shown in this article will give the chemical plant man a rough idea of the present field; but who can guess what will happen in the field of electrical application to the chemical industry in the next few years?

Wilmington, Del.

Molding Practice for Aluminum Alloys*

Aluminum Casting Alloys Are Light and Hot Short, Therefore It Is Necessary to Use Free Venting Molds and Cores Which Crush Easily — Low Gates and High Risers, Together With Free Use of Chills on Thick Sections, Necessary for Sound Casting

ALUMINUM can be cast by the same general methods used in the casting of brass and bronze, but with certain modifications dependent upon its various physical properties. The purpose of the following information is to point out where these changes in method should be made and to state in general what is considered the best practice.

Molding Sand

In the selection of molding sand for an aluminum foundry the texture or mechanical composition of the sand is much more important than its chemical composition. A good molding sand should be neither "close" nor "open." If it is too fine it will not be free-venting and will, therefore, prevent the escape of air, steam and gases. On the other hand, it should not be too coarse or it will fail to give a smooth and clean surface to the casting.

The sand most generally used in aluminum founding is Albany OO molding sand. The clay in this sand forms such a good natural bond that no artificial binder, such as flour, treacle, dextrin or sulphite-lees, is needed. All that is necessary is to riddle the sand through a No. 4 sieve to remove all large foreign substances, to moisten it and to mix it thoroughly; then it is ready for use. Just enough water should be added to the sand to give it the required bond; additional water only obstructs the escape of the steam generated and the gases given off by the molten metal.

No specially prepared facing sand is required. When riddled through a sieve ranging in size from No. 8 to No. 20, depending upon the casting in question, the regular molding sand makes a good facing for the pattern. Additions to the sand for the purpose of forming a smoother surface for the mold and increasing the bonding qualities of the sand are harmful, for they make the sand impervious to steam and gases. The practice of facing the pattern with good sand and using almost any kind of sand as a filler-up is a bad one. The saving realized in the cost of sand is more than offset by the loss in defective castings due to poor molds.

The usual method of putting the new sand into service is to add small quantities of it at frequent intervals to the old sand. With each additional use the molding sand loses some of its bond. The molten metal drives off the water and "kills" the clay which comes in immediate contact with it. Inasmuch as sand tempers best when it is steaming, water and new sand are usually added immediately after the castings have been shaken out.

Principles to Observe

Careful observation of the two following characteristics of the common aluminum alloys will obviate most of the troubles of the molder: Aluminum alloys are light, for iron or brass are two to three times as heavy; and they are brittle or "hot short" at temperatures slightly below the melting point. In casting aluminum practically every modification of the usual brass foundry practice is attributable to one or the other of these reasons, and any steps taken which provide for these peculiarities are in the right direction. A consideration of the first characteristic will explain why certain practices in ramming, venting, gating and feeding the mold employed in brass foundries cannot be used unmodified when casting aluminum. Aluminum is so light that it cannot rid itself of absorbed gases and drive off the steam as readily as brass. Observance of the second characteristic will prevent cracks in the castings due to hard cores or molds. If the cooling metal when in its "hot short" condition encounters very much resistance to further shrinkage it will almost invariably crack.

Because of the lightness of aluminum alloys the mold may be made in a snap flask which may be removed when the mold is completed. The sand should be rammed as lightly as is consistent with safe handling and pouring of the mold. Additional ramming serves only to create an impervious wall which will prevent the escape of the imprisoned air, steam and gas, forming blowholes, and producing a rough surface to the casting because the metal cannot lie close to the mold. Hard ramming is also objectionable, as it prevents the mold from giving when the metal shrinks, for it must be remembered that certain parts of the mold, as well as the cores, are called upon to give way to the metal in contraction. To help the mold to keep its shape after the flask has been removed, the outside of the mold may be rammed fairly hard, but the hard ramming should never extend to the sand immediately adjacent to the pattern. A close adherence to the principle of light ramming will probably obviate most of the aluminum molder's troubles.

The mold should be well vented for the same reason that the sand should be rammed lightly. In the case of large castings especially, the minute openings resulting from the porosity of the molding sand are an inadequate outlet for the steam and gases, and venting must be resorted to. For small castings vents are often unnecessary.

Low Gates and High Risers

No set rules can be laid down to govern the number, size and location of gates, for each particular casting presents a different problem. This must be left largely to the discretion of the molder, who should always bear in mind the two characteristics of aluminum alloys before mentioned. One or two general suggestions, however, may be given. A liberal fillet should always be employed where the gate connects with the casting in order to avoid drawing just beneath that point. If increasing the size of the fillet does not entirely eliminate trouble from drawing, the gate should be so

*From sales department condensed data prepared by the Technical Department, Aluminum Company of America.

located that the unsound part of the casting caused by the draw will do the least amount of harm. If possible, it is also good practice so to locate the gate that when the mold cavity is filled with metal, the length of the path traveled will have been such that the heavy sections will have filled first and will be colder than the light sections. It is also generally true that the gate should enter the casting at a low rather than high point, for less air is imprisoned in the mold by gradually rising metal than by falling metal. Due to mechanical difficulties, however, all these suggestions are subject to a limited application.

Risers are usually attached to those parts of the casting which solidify last. The parts which first solidify draw metal from the larger, slower-cooling sections, so the latter sections must find a source of supply sufficient to provide metal for both its own shrinkage and that of the smaller fast-cooling sections. Risers are constructed to create such a source of supply. They must be so located and of such a size that they will remain molten longer than the casting. Otherwise, they simply act in the same way the small sections of the castings do, and draw metal from the large section, making matters worse rather than better. If possible, the riser should enter the casting at its highest point so that the air and dross may be forced up into the riser instead of being trapped in the casting. By increasing the height of the riser, the pressure of metal may be increased, and consequently sounder and sharper castings will result. On small castings risers are seldom necessary.

Chills may also be used as a safeguard against injurious shrinkage, especially in large castings of irregular section. Where light sections of the casting join heavy sections, uneven cooling takes place. The light section cools first and, in cooling, is fed with metal from the still liquid heavy section. When the heavy section finally cools it draws from the light section, causing sponginess and sometimes cracks in the junction between the two. To correct this tendency some means of artificial cooling must be adopted which will make the heavy section set as fast as the light section. Chills are used for this purpose, and the pieces of metal are so placed in the surface of the mold that they will come in immediate contact with the heavy section of the casting.

It will thus be seen that chills serve much the same purpose as risers, the difference lying principally in the method employed. Risers prevent sponginess and cracks in the junction between two sections by supplying the larger section with molten metal as it shrinks, while chills accomplish the same result by making the two sections cool at an equal rate. Chills are also used for other purposes. They are often employed to give a hard, smooth surface to certain parts of the casting. A harder surface than is usually produced is often necessary if a part of the casting is to be subjected to unusual wear, while a smooth surface often eliminates machining.

Soft Cores Essential

Cores for aluminum castings should be made as soft as is consistent with safe manipulation. Because of the "hot short" condition of alloys at high temperatures, it is particularly important that they give way to the shrinkage of the cooling metal. A good core should be hard enough to be safely handled at ordinary temperatures, but should soften and crush when subjected to the intense heat of the molten metal, since the slightest resistance to the shrinkage of aluminum when it is in this fragile state will usually result disastrously.

A good core sand should consist of a mixture of sharp sand and molding sand in varying proportions held together by some such binder as rosin, flour or core oil. The sharp sand furnishes good venting qualities to the mixture. The molding sand adds strength to the cores before they are baked and produces a smooth surface to the casting. Rosin is probably the best binder to use, for on coming into contact with the molten aluminum it softens, permitting the core to give as the casting shrinks. In some core sands a small amount of flour is used in addition to the rosin to assist in binding the mixture together until the cores are baked. The rosin has no binding power until it has first been melted and then allowed to harden. Linseed oil and various patented core oils are also successfully used as binders by some foundrymen.

A sand mixture for cores that will crush and prevent cracking is composed of the following ingredients:

Sharp sand	45	parts
Molding sand	45	"
Powdered rosin	2	"
Flour	1	"

After this mixture has been moistened to the correct degree of dampness, it is ready for use. The core should be rammed lightly and should be freely vented. This precaution is more important in the construction of the cores than of the mold proper, for, unlike the mold, the core is almost completely surrounded by the metal. The completed core should be sprayed with molasses water, baked in an oven hot enough to melt the rosin thoroughly, and then given a soapstone wash to secure a smooth finish.

Green sand cores are molded from the regular sand which is used for the mold itself, and require no binder other than water. They are skin dried with a blow torch immediately before setting in the mold. At present green sand cores are used principally for large body cores in casting automobile crankcases and oil pans. With proper development there is no reason why their use cannot be greatly extended to such parts as manifolds, bearings, flywheel housings and gear cases. They cannot be used for small cores of intricate shape for ramming up, nor in places where the core print support is limited in size or position.

Green sand cores, since they are made of the same material as the mold, have an equivalent chilling effect which promotes uniform solidification of the metal. Baked sand cores, on the other hand, have but a fraction of the heat-absorbing power of green sand, therefore induce non-uniform solidification with the resultant shrinkage crack.

The crushing strength of green sand cores is from 1 to 3 lb. per square inch, or about 1/100 that of baked sand cores. This is an important consideration in connection with the very weak condition of the metal just below the solidification point when the solid shrinkage is taking place.

Die Casting

The art of die casting is not new. For many years zinc, lead and tin have been successfully cast in this manner. Aluminum die castings, however, are of comparatively recent development. A copper-aluminum alloy is most frequently used with copper content running from 8 per cent to 10 per cent.

It would naturally be supposed that castings made under pressure would be dense and homogeneous. On fracture, however, it is found that only the surface or skin of the casting is dense and close-grained, while the inner structure is porous. This applies particularly to the larger castings; smaller ones can usually be cast very satisfactorily. Another cause of trouble has been the cracking of the casting due to resistance to shrinkage offered by the metallic cores, but this trouble is largely removed by the use of collapsible cores.

Test Bars

It is important to standardize methods of testing aluminum castings in order that results obtained in one foundry may be comparable with those obtained in another, or that tests made one day may check up with those made at another time. The test specimen recommended by the Society of Automotive Engineers and the one most generally used is a cast-to-size bar $\frac{1}{2}$ in. in diameter at the breaking section and filleted to a $\frac{3}{4}$ in. diameter threaded end. The fillet should not be less than $\frac{5}{8}$ in. radius. The test bar should be cast in sand, the use of chills or artificial means of cooling is prohibited. The gage length for aluminum should be 2 in.

The American Society for Testing Materials recommends a similar bar, but machined to size rather than cast to size, in order that the diameter at the breaking section may be more accurately measured. In ordinary foundry practice the increased accuracy of the test due to machining the breaking section and threading the ends is not considered sufficient to pay for the cost of machining, and so the test bar is usually cast to size and pulled in wedge grips. Even the ideally designed and cast test specimen is not without its limitations, for it can be expected to give only approximate results for the metal in the casting which it is supposed to represent.

The test bar checks the history of the metal up to the time it goes into the mold. It gives no check whatever upon the molding variables, except when the bar is attached to the casting, when it reflects certain, but not all, of the variables, and in addition it gives no check on the design of the casting. The only way in which to secure such checks is to cut the casting up into parts and take test specimens from each part. Such an experiment will indicate considerable variations in the physical properties of the different parts, for unless molding practice and design are perfect the physical properties of a casting are bound to vary from point to point.

These variations are due to shrinkage, gating methods, the chilling effect, the personal element in foundry work and the design. When it is understood thoroughly to what an extent the physical properties of a casting are subject to control by variations in the melting conditions, the molding practice and the design, a long step will have been taken toward a better adaptation of castings to the purposes for which they are intended.

Heat-Temperature Curves of Metals

The adjoining diagrams, Figs. 1, 2 and 3, are taken from an article by J. F. Shadgen in *The Iron Age*, July 27, 1922, p. 218. In turn, that author is indebted to recent investigations by Wuest, Meuthen and Duerrer[1] for the data from which the diagrams are drawn, and the copious tables computed. "The investigators used the purest forms of metals commercially available, and an apparatus similar to the vacuum calorimeter of

Synopsis of Recent Chemical & Metallurgical Literature

Determination of Modulus of Elasticity and Limit of Proportionality

R. Guillery[1] proposes a testing machine which will automatically register the modulus of elasticity of the specimen, and after this has been determined and checked, will then indicate the stress at which this modulus loses its constancy—i.e., the limit of proportionality.

Tension is put upon the test-piece *A* (Fig. 1) by a clutch attached to the piston of a hydraulic cylinder. Elongation is transferred by means of the link motion sketched at *B* to a proportional distention of the diaphragm at *C*, and is measured at a magnification of 2,000 by change in the elevation of the liquid in the attached level.

Liquid in the main cylinder is connected by a pipe to another cylinder actuating piston *F*, which works against a calibrated spring *G*, thus deflecting it an amount proportional to the stress on the test-piece *A*. This deflection, in turn, is transmitted by the lever system shown at *E* to a second diaphragm *D*, also connected to the level.

The arrangements are so made that an increase in elevation of the liquid in the measuring tube caused by contraction of *C* is counteracted by a simultaneous decrease in level caused by expansion of *D*. Exact balance may be had by adjusting the position of the little roller separating the upper and lower levers at *E*. When this is done, variation of the tension on the test-piece will cause no change in the water level, since within the elastic limit, stress and strain are proportional. Thus, the modulus of elasticity may be read from the position of the roller against a scale attached to one of the levers *E*.

Everything being in adjustment, as noted, the water level is unchanged as the load on the test-piece increases. The moment the proportional limit is reached, however, the water level shows a fluctuation, and the corresponding stress can be figured from the pressure existing in the main cylinder.

Lowered Transformation in Quenched Steel

If carbon steels, containing from 0.4 to 0.9 per cent C, be cooled extremely slowly, A_1 occurs at 726 deg. C. Normal rates of cooling lower this to a narrow range at approximately 700.

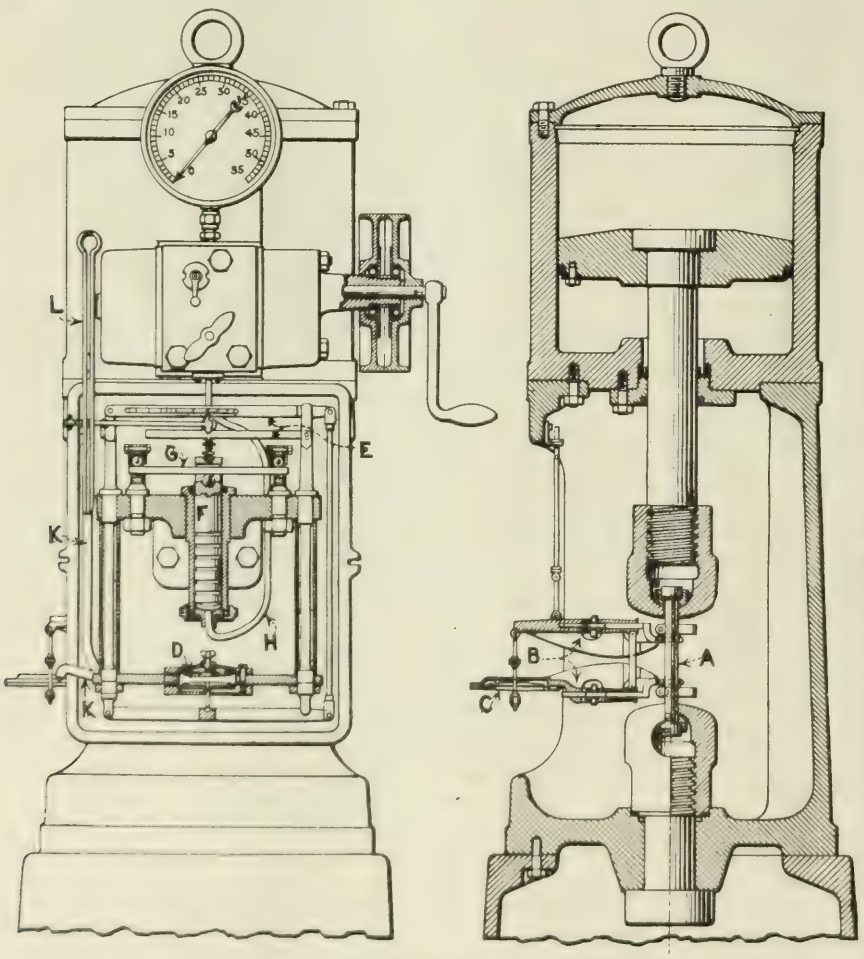

FIG. 1—DIAGRAM OF MODULUS INDICATOR

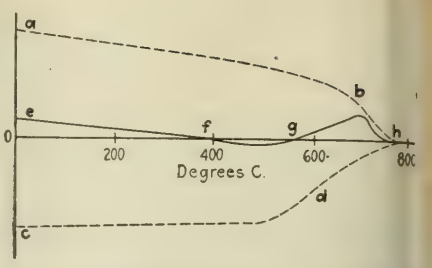

FIG. 2—TRANSFORMATION FORCES I CHROMIUM STEEL

More speedy cooling lowers it stil further and widens the range until i centers at about 550 deg. C., and th lowered transformation has been la beled Ar_1'. Quenching still more rap idly, as in jets of water at 70 deg., th lowered transformation splits, a secon portion called Ar_1'' occurring at a rang beginning at about 300 deg. C. or ever lower. Still more drastic quenching suppresses Ar_1' entirely and lowers Ar_1'' another 100 deg. The same kin of phenomena occur in steels containing 0.9 per cent carbon and 10 per cent chromium or nickel, except, due to sluggish rates of change, they may be observed at moderate cooling speeds.

Kôtarô Honda and Tario Kikuta* have studied these phenomena, and conclude that Ar_1'' and Ar_1' are both merely retarded A_1 transformations—i. e., the change of austenite through martensite to pearlite. They find that if the temperature is held constant at some temperature within Ar_1', the entire transformation completes itself and Ar_1'' does not appear. In the same manner if Ar_1' is passed fairly rapidly, and the temperature held constant somewhere within Ar_1'', this lowered transformation also continues to completion—a longer time is required as is consistent with molecular inertia at such low temperatures. However, in the chromium steel, Ar_1'' does not proceed if the temperature is held constant for hours between Ar_1' and Ar_1''.

Let us assume that the forces tending to produce a transformation vary with the degree of undercooling somewhat as sketched in *ab* (Fig. 2). The retarding influences, such as viscosity, increase the inertia with falling temperature, somewhat as *cd*. The arithmetical sum is plotted in *efgh*, and for such conditions it is evident that one transformation which initiates at *h* may occur in two steps, *h* to *g*, and *f* to *o*. Between *f* and *g* the net transforming force is negative, so that a stay in this region would not suppress Ar_1'' The illustrated case conforms to chromium steel. Curve *ab* for nickel and carbon steels has sufficiently larger ordinates than *cd* so that portion *fg* lies just above the horizontal axis. Therefore, while the transformation is stepped if the cooling speed is right, it will always complete itself at any temperature if sufficient time be given. Steels with 26 per cent nickel are non-mag-

*Fifty-ninth report of the Iron and Steel Research Institute; *Science Reports*, Imperial Tohoku University, vol. 11, p. 105. Also read before the May, 1922, meeting of the British Iron and Steel Institute.

tic at room temperature, but become agnetic in liquid air. Curves *cd* for ich steels have larger ordinates at gh temperatures but smaller at low, that curve *eh* is above the horizontal kis only at very low temperatures. xactly the opposite is true for Had-ld's manganese steel, which is non-agnetic in liquid air, but becomes agnetic after annealing at 550 deg. C.

Bureau of Mines Studies Economic Status of Carbon Black

Forty billion cubic feet of natural gas used annually in the United States the manufacture of carbon black, tates the Bureau of Mines, which has ompleted a study of the subject. Car-on black is used extensively in the ubber industry, something like 20,000,-00 lb. going annually into the manu-acture of automobile tires. From 0,000,000 to 12,000,000 lb. of carbon lack is used annually in the manufac-ure of printers' ink, and from 4,000,000 o 5,000,000 lb. in the making of stove olish. The product enters also into he composition of black and gray paint, honograph records, carbon paper, rayons, typewriter ribbons, glazed aper, tarpaulins, black leather, arti-icial stone and insulating materials. In ormal times the United States exports robably 10,000,000 lb. of carbon black n a year.

Confusion exists in the use of the erms lampblack and carbon black. Car-on black is the fluffy, velvety-black igment produced by burning natural as with a smoky flame against a netal surface. In its physical char-cteristics it is entirely different from ampblack, which is made by burning il or other carbonaceous material with nsufficient air and collecting the moke in settling chambers. The pro-ess of manufacture most widely used at present is the so-called channel sys-em, in which the black is deposited on he smooth undersurface of steel chan-nels by lava-tip burners. The mech-anism is inclosed in sheet-iron buildings in order that the amount of air may e regulated.

It is generally conceded that the most important use that can be made f natural gas is for domestic purposes. Whether gas is of greater economic alue for the manufacture of carbon lack than for other industrial purposes s a question that will depend on the onditions existing in each locality here a large supply of natural gas is vailable.

The policy of the Bureau of Mines is hat carbon black be made when gas is roduced in isolated sections with no resent or reasonably prospective mar-et for gas being produced, when gaso-ine has been extracted, and when prac-ical and modern and improved methods re used. At present there is consider-ble agitation for and against laws estricting the use of natural gas for he manufacture of carbon black. The natter has been the subject of consider-ble agitation and legislative considera-ion in Wyoming. The carbon-black in-lustry has been established in Pennsyl-vania for over 40 years, and in West Virginia for more than 20 years. The latter state still produces more than 50 per cent of the entire supply. Neither of these states has passed any laws restricting the use of natural gas for this purpose.

The carbon-black manufacturers claim that they use the best manufacturing processes that have been developed and that they produce a commodity of acknowledged utility. They have also provided a market for gas in isolated regions and in so doing have many times prevented conditions that would otherwise have resulted in waste. In certain isolated districts they have furnished small communities with natural gas whose consumption they assert was not sufficient to warrant the building of a pipe-line system.

The Bureau of Mines considers that the utilization in the manufacture of carbon black of low-pressure gas, of gas escaping into the air from natural-gas gasoline plants, gas in distinctly isolated districts, and gas in fields that have been abandoned by other gas companies on account of low pressure, is in reality often a conservation measure. It is preferable to the practice of letting the gas go to waste in the air or to plugging improperly the wells so that the gas sands can be damaged from flooding by water.

More efficient processes should be devised for the manufacture of carbon black. Thermal decomposition offers an interesting field for research as a possible means of increasing the relative efficiency of the industry. In the future it is probable that at some plants the waste heat will be utilized profitably.

The results of a study of the manufacture, properties and uses of carbon black, made by Roy O. Neal, consulting engineer, and G. St. J. Perrott, physical organic chemist, are given in Bulletin 192, just issued by the Bureau of Mines.

Vitamine Content of Canned Foods Compares Favorably With Cooked Food

A bulletin recently prepared by Dr. E. F. Kohman, of the Research Laboratory of the National Canners' Association, brings together all the research literature relative to the effect cooking has on vitamines. This research demonstrates that canned foods supply the vitamines as abundantly as the same foods cooked in the ordinary way. The vitamine content is the greatest when foods are at the proper stage of maturity for consumption and decreases when the foods are held for a period of time. Canned foods are processed in vacuum, while foods cooked on the stove are exposed to the air, which is the cause of a considerable loss of vitamine C. From the experimental evidence now available, canned foods are found to be practically as rich in vitamine A and B as the corresponding fresh raw products. In acid products, such as tomatoes and fruits, there is only a negligible destruction of vitamine C by ordinary cooking or in the canning process.

Book Reviews

THE CHEMISTRY OF THE NON-BENZENOID HYDROCARBONS. By *Benjamin T. Brooks, Ph.D.* New York: The Chemical Catalog Co., Inc. 1922. 612 pp. 23.5x26 cm. Price $7.

"The beautiful, interesting and often facile chemistry of the benzene hydrocarbons has somewhat overshadowed the chemistry of the aliphatic open chain and cyclic non-benzenoid hydrocarbons." Dr. Brooks, in the opening sentence of the preface, thus expresses his conviction that the chemistry of the hydrocarbons has in the past been too largely aromatic chemistry. To right the balance, the author presents us with a 600-page treatise which brings together a mass of detail concerning the properties and behavior of non-benzenoid hydrocarbons, both open chain and cyclic, saturated and unsaturated. It is no mere catalog of substances and processes; the author "has endeavored to show the close relationships which hold generally throughout the chemistry of the non-benzenoid hydrocarbons and, on the other hand, to point out that the chemical behavior of the more complex hydrocarbons of the paraffin series and the alicylic hydrocarbons cannot be assumed from the chemical behavior of a few of the simpler hydrocarbons," and he has done his task well. It is a large and varied field—paraffins, olefines, hydroaromatics and the multitudinous terpenes; petroleum refining, synthetic rubber and camphor—but each portion is ably handled with particular reference to the most modern developments.

The book should be of great value to those who are in any way dealing with non-aromatic hydrocarbons, whether from the industrial or the purely scientific standpoint. No attempt is made to consider all the complexities of such a subject as petroleum refining, but nevertheless there are several pages devoted to the pyrolysis of the paraffins and a very interesting discussion (9 pages) of the chemical aspects of certain steps in the refining, particularly the sulphuric acid treatment. The several processes for synthesizing camphor from turpentine are critically considered and clearly presented. A special chapter is devoted to the physical properties of the hydrocarbons, while another deals with their physiological action.

The organic chemist whose chief work lies in other directions will probably find the book almost as valuable as will the specialist. There are very few books or general articles which deal with the aliphatic hydrocarbons and none which can so conveniently serve as a reference book for this subject. The alicylic compounds and terpenes have been exhaustively reviewed before, particularly by Aschan, but a great mass of difficult and complicated work has appeared since the most recent

of these special books was published. Dr. Brooks has made a special effort to include the modern work in terpene chemistry and, for example, has brought the discussion of the Wagner rearrangement up to date by including Meerwein and Lipp's work (1920). For this reason and because of the general way in which the subject has been treated, the five chapters on terpenes make an excellent textbook for a student of this difficult field. The chapter on rearrangements is of considerable theoretical interest. It is to be regretted that it does not in some way contain cross-references to other cases of rearrangements which are dealt with elsewhere in the book. In fact, a greater number of cross-references throughout the monograph would have helped in correlating the various branches of the subject which necessarily overlap.

The typography is not as good as it should be. Some of the structural formulas are very carelessly printed, the carbon "bonds" in some instances being so irregular that the meaning of the formula is almost obscured. This is, however, a relatively small point and is perhaps counterbalanced by the large number of equations and structural formulas which are given, and which, as always, are of great assistance to the reader. JAMES B. CONANT.

ENGINEERING STEELS. By *Leslie Aitchinson*, Consulting Metallurgist of the Air Ministry of Great Britain. 397 pp. London: MacDonald & Evans. New York: D. Van Nostrand Co., 1921. Price $6.

"Engineering Steels" is written from the point of view of a mechanical engineer and designer rather than from the point of view of a metallurgist and is a valuable addition to the literature on this subject. It is clear and concise and points out the need for and importance of co-ordinating the wants of the engineer in his design with the problems of the metallurgical engineer, the heat-treating expert and the physicist. Dr. Aitchinson reviews the important factors to be met by the metallurgist in determining the proper composition for standard and special steels the heat-treatment necessary to produce the best microstructure, and the general subject of testing the steel for chemical and physical properties before applying it to the service for which it is intended.

A brief review is also given of the steel-melting processes in common use, and some of the advantages and disadvantages of each are pointed out. The author discusses the casting of the ingot, the flow of the metal under the roll, hammer or forging press and the effects of slag in the metal while being worked and its influence on steel when under stress.

The chapter on heat-treatment describes, in a concise manner, just what happens in plain carbon and alloy steels and causes them to respond to heat-treatment. The data include time-temperature cooling curves and curves showing the physical properties resulting from different drawing temperatures for different carbons in plain steel and for different alloys in alloy steels.

Photographs of special testing apparatus, macrostructures and microstructures of different classes of steel under varying conditions of manufacture and treatment are arranged in the appendix at the end of the book. This feature gives added usefulness in having much detailed data available, yet removed from the text proper.

In general, this book is a concise compilation of data on steel arranged in good order for students of steel metallurgy as well as the busy engineer who must decide quickly what material he will use and what tests he will require. T. D. LYNCH.

THE JOURNAL OF THE INSTITUTE OF METALS. Edited by *G. Shaw Scott*, secretary. Vol. 27. The Institute, 36 Victoria St., London, S. W. I. 630 pp. Price, 31s. 6d. net.

Despite the fact that the present volume corresponds with the inauguration of Leonard Sumner, a manufacturer, as president, the most of the original papers presented are what might be called "theoretical treatises on such impractical things" as recrystallization (85 pages) equilibrium of the aluminum-zinc system, or rate of combination of copper and phosphorus. On the other hand, some manufacturers would not be altogether disappointed, since they have doubtless found that recrystallization has much to do with the permanence of their product and its immunity from season cracking. This very subject is discussed at length in the same volume by Messrs. Moore and Beckinsale, while Dr. Guy D. Bengough's recent pamphlet (designed entirely for "practical" men) on "Corrosion and Protection of Condenser Tubes" was discussed at length by many members.

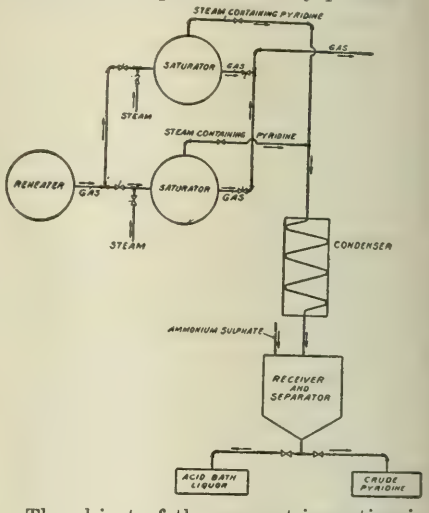
An important paper on "Mechanical Properties of Nickel-Silvers," by Prof. F. C. Thompson, is also included. Abstracts from current literature taking up 220 pages complete the remainder, a balance between theory and practice or between manufacturer and user which has been the aim of the Institute since the first. How well this aim has been fulfilled was commented upon by the new president, citing the fact that during 1921, a year of greatest trade depression, the membership increased from 1,298 to 1,410. He ascribed the fact that the cessation of the war brought no drop in the widespread interest in the Institute to the "open-door" policy inaugurated during the war, when every manufacturer was driven by the press for munitions to open his plant and discuss his trade secrets with his former competitors. The value of the Institute of Metals as a common meeting ground was very apparent then, and apparently has not yet been forgotten. E. E. THUM.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Recovery of Pyridine—In the manufacture of byproduct coke and illuminating gas, pyridine bases are present in the crude gas and are finally found in the tar, ammonia liquors, ammonium sulphate, light oils, etc. Some of the higher boiling pyridine bases are separated in the tar, but the gas after the removal of the tar contains a considerable proportion of them. A large proportion of these pyridine bases are absorbed in the sulphuric acid bath along with the ammonia in the saturators as employed in the direct or semi-direct ammonium sulphate recovery process.



The object of the present invention is to recover more economically the pyridine bases from the ammonium sulphate solution and particularly to accomplish such recovery with but little interference in the regular operation of the byproduct plant. In the process they dispense with the treatment of the acid liquor bath with ammonia and recover the pyridine directly from its acid solution. While the recovery of the pyridine from a strong acid solution is difficult, it is found that pyridine can be steam distilled readily from an acid bath of low acidity. This can be accomplished readily with solutions of not more than 2 per cent acidity. The distillation of the pyridine from such solutions can be more advantageously accomplished by having the solution substantially saturated with the ammonium sulphate at its boiling point.

In the drawing is illustrated schematically the application of the present invention to the pyridine recovery in a byproduct plant employing the direct or semi-direct ammonium sulphate process. (1,414,441; Frederick W. Sperr, Jr., and Ralph L. Brown, of Pittsburgh, Pa., assignors to the Koppers Co. of Pittsburgh, Pa., a corporation of Pennsylvania. May 2, 1922.)

Nitrocellulose Stabilizer — A novel method of controlling the diphenylamine content of smokeless powder has been patented by George Rocker for E. I. du Pont de Nemours & Co. The stabilizer is introduced in the process of washing the surplus ether from the nitrocellulose colloid. A 60 per cent ethyl alcohol solution is used and is made up to contain a certain percentage of diphenylamine which is calculated according to the formula $y = \frac{X-B}{4.5}$, where y equals the necessary percentage of diphenylamine in the solution, X equals the percentage of diphenylamine desired in the finished powder, and B equals the percentage of diphenylamine already in the powder. The diphenylamine-alcohol solution is calculated so that the proper amount of the stabilizer will be introduced into the powder, but no more. The excess solution is washed out by water. (1,424,212. Aug. 1, 1922.)

Gas Scrubber.—In the passage of gas or vapor through a scrubber, the back pressure created against the passage of the gas is in some cases of considerable importance. Such a case would be, for example, where a small amount of ammonia was to be absorbed in water from a large amount of gas; or again, where it is required to cool a large amount of water and the loss of water head becomes of importance.

This invention has for an object the production of a thorough contact between vapor or gas and a liquid or liquids. It is considered that by means of this apparatus, this contact can be obtained without the necessity for a high head on the liquid.

Th essential point of difference between this scrubber and other scrubbers made for a similar purpose is in the design of the diaphragm. The shell of the scrubber is composed of cylindrical sections united at flanged joints. At the bottom of each section is an inlet for gas and an outlet for scrubbing liquids. At the top of each section is an outlet for gas and an inlet for scrubbing liquids. On the inner periphery these sections are flanged to provide trough-like elements. In the interior of the section is a perforated diaphragm with its edges sealed by liquids in these trough-like elements. The perforations in the diaphragm are small and are adapted for the passage of gas without much, if any, passage of liquid.

These diaphragms are arranged so they may be set level or at an angle and means are provided for varying this angle. Liquid coming from the top is received on the diaphragm and covers it in film form. The thickness of this film depends on the angle at which the diaphragm is set and the amount of liquid supplied. The gas passes upward through the perforation and through this liquid film, producing thorough contact between the liquid and the gas. With the small perforations provided in the diaphragm, practically all the liquid on this diaphragm flows to the liquid seal at the discharge end and thence to the section below.

It is found in practice that the passage of gas through uniform perforations, such as occur in the diaphragms described above, is substantially equal at all points. For this reason it is claimed that maximum contact of liquid and gas is obtained with the minimum amount of back pressure. (1,419,867; Wilbur G. Laird, New York, assignor to Henry L. Doherty. June 13, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Ceramics—Grains of natural or artificial corundum, or composite artificial aluminates melted in the electric furnace, are incorporated in ceramic compositions, particularly those used in the manufacture of electric apparatus such as insulators, sparking plugs, pulleys, switchboad plates, tubes, boxes and resistances. (Br. Pat. 177,160; not yet accepted. L. A. Cordenot, Rosny-Sous-Bois, France. May 10, 1922.)

Metallic Chlorides—Inorganic chlorides are obtained by passing chlorine containing sulphur chloride over a heated mixture of an oxide and carbon, the production of silicon and aluminum chlorides being particularly described. When aluminum chloride is prepared, the first product is a sublimate containing an addition product of sulphur chloride with aluminum chloride from which the two chlorides are separated by distillation, preferably under reduced pressure. The mixture of chlorine and sulphur chloride may be made by passing chlorine through an evaporator containing sulphur chloride. Alternatively, the sulphur chloride may be formed *in situ*, for example by adding sulphur compounds such as pyrites or a sulphate to the mixture of carbon and oxide. (Br. Pat. 176,811. Consortium für Elektrochemische Industrie-Ges. Munich. May 10, 1922.)

Dialkyl Sulphates—Dialkyl sulphates are obtained by heating the corresponding alcohols or ethers with alkali pyrosulphates or chlorsulphonates or mixtures thereof, and distilling *in vacuo;* or the alcohol vapor may be passed over the heated pyrosulphate. Examples of both methods are given as applied to the production of diethyl sulphate from ethyl alcohol and sodium pyrosulphate. Methyl, propyl and butyl alcohols and ethers are also specified as initial materials. (Br. Pat. 177,189; H. Dreyfus, London. May. 17, 1922.)

Phosphates—A modification of the process in which a mixture of crude phosphate, alkaline sulphate and a loosening substance is treated with hydrochloric acid gas consists in treating the mixture of phosphate and loosening substance with hydrochloric acid gas without previous admixture of alkaline sulphate. The latter is added afterward to convert the calcium chloride formed into gypsum. In this case the addition of an indifferent substance such as sand, gypsum, infusorial earth or dry brown coal to the mixture of phosphate and loosening substance prevents caking during the course of the reaction. In an example, 100 kg. of Florida phosphate mixed with 40 kg. of crude lignite and 50 kg. of sand are submitted to the action of hydrochloric acid gas, and the product is mixed with 80 kg. of ammonium sulphate. (Br. Pat. 177,496, not yet accepted; F. Risberg, Mannheim. May 17, 1922.)

Ethylene Derivatives — These are manufactured from a gaseous mixture containing ethylene and a halogen or an acid chloride using a porous charcoal as a catalyst either with or without a halogen carrier such as chlorides of antimony, sulphur, phosphorus, etc. According to examples, the ethylene content of coal gas is caused to react with chlorine with and without antimony pentachloride, with bromine and with phosgene, forming respectively ethylene dichloride, ethylene dibromide and beta-chlorpropionyl chloride. (Br. Pat. 177,362; Bayer & Co., Leverkusen, Germany. May 17, 1922.)

Viscose—In the preparation of viscose, the caustic alkali solution is cooled to a temperature not exceeding 5 deg. C., for example, to —2 deg. C., before addition to the cellulose material. To assist the penetration of the caustic alkali solution into the cellulose, the air in the vessel in which the treatment is carried out may be evacuated or may be replaced by a gas that is soluble in or reacts chemically with the alkali solution, such as ammonia gas or sulphur dioxide. (Br. Pat. 178,152. W. P. Dreaper, London. June 8, 1922.)

Cellulose Acetate—Artificial filaments or films are prepared from cellulose acetate solutions, in particular the solutions in acetone, by coagulating the formed filament or film in a bath containing a thiocyanate such as ammonium, potassium, sodium or calcium thiocyanate. By this process the filament is of improved strength and elasticity and granulation is obviated, and in the case of filaments it is possible to employ large spinning orifices and to draw out the filaments to the fineness of natural silk. Plastifying agents such as benzyl alcohol and other additions may be made to the cellulose acetate solution. (Br. Pat. 177,868. British Cellulose & Chemical Manufacturing Co., London. May 31, 1922.)

Imitation Milk—An imitation milk, which may be concentrated or dried like cows' milk, is prepared from coconuts by extracting the endosperm with the water of the coconut. For this purpose the endosperm of fresh coconuts, preferably at the stage of ripeness at which the liquid is barely perceptible on shaking, or clean copra, is ground up with the water of the coconut, or it may be comminuted and the water afterward added. The water, with the material it has taken up, is then expressed in any known way, and the resulting liquid concentrated at a temperature not exceeding 80 deg. C. To

increase the protein and sugar content a portion of the coconut milk from which oil has been removed by decantation may be added to the liquid before concentration. (Br. Pat. 177,927. L. M. Smith, Hawaii. May 31, 1922.)

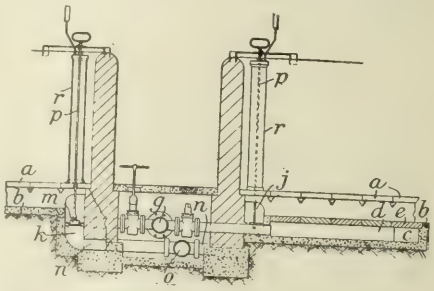
Lithopone — In making lightproof lithopone, the zinc salt solution, the baryta lye and the water used in the process are purified and clarified by producing small quantities of a purifying medium in the liquids. For example, a small quantity of an iron or aluminum salt is added, and precipitation is effected by adding a slight excess of a carbonate, phosphate or hydrate, the liquids being then boiled and filtered. The barium sulphide solution is obtained by treatment of a baryta lye, purified as described above, with sulphuretted hydrogen. (Br. Pat. 176,377. Cordes & Co. Ges., Berlin. May 3, 1922.)

Cellulose—In the preparation of cellulose capable of forming highly viscous solutions, the lignin substances are converted by treatment with chlorine into a form soluble in cold dilute soda lye, while the cellulose remains unaltered. Straw is first boiled with dilute hydrochloric acid such as is obtained from the chlorination process. Wood is first boiled with caustic soda or milk of lime, and may be treated as shavings with chlorine diluted with an indifferent gas or applied alternately with such gas. In treating wood as chips, chlorine under pressure is used. The hydrochloric acid produced by the chlorination reaction may be reconverted into an impure chlorine and used again. (Br. Pat. 178,196. H. P. Waentig and J. O. W. Gierisch. Dresden. June 8, 1922.)

Motor Fuel—A motor fuel is produced by agitating, say, 3 to 5 lb. of calcium carbide in a pressure-resisting vessel with 9 gal. of commercial alcohol and, say, 1 gal. of acetone, and permitting the mixture to stand with occasional shaking until the acetylene is absorbed. The liquid is cleared from the bulk of the lime by carbon, manganese dioxide or other insoluble flocculating agent. A fuel of the composition specified contains over 12.5 times the volume of acetylene and 0.025 to 0.05 per cent of lime. (Br. Pat. 178,498. S. W. Blake. South Africa. June 14, 1922.)

Continuous Crystallizer—In crystallizing and separating the salts contained in a mixed solution, the solution is evaporated by being run down a sloping table, and the salts separate on the table in order of their solubilities, the least soluble being deposited first. The table, which may be cambered, has projecting edges, transverse inclined baffles and intermediate spreading baffles. The table may be mounted on trunnions so as to be turned to discharge the salts, and may be combined with other tables in triangular or other form so that, on being turned, another table surface is brought into position. The table may be heated by electric resistances extending along it or by other means, and may be covered and the water vapor evolved be drawn off and condensed. Glass covers may be used and the heat of the sun used to effect evaporation. (Br. Pat. 178,263. T. G. Tulloch, London. June 8, 1922.)

Paper Making—In the manufacture of paper, the under side of a mass of stuff from which bleaching liquid has been partly drained is subjected to a vacuum to render the bleaching uniform throughout the mass. As shown,



the spaces between the false floors *a* and true floors *b* of a series of bins are connected to a sump by drainage channels *j*, valves *m*, ducts *k* and branches *n* of a pipe *o*. Transverse and longitudinal channels *c*, *d* in the floor *b* are connected by valve-controlled pipes with a main pipe *g* of air-exhausting apparatus. The stem *p* of each valve *m* is inclosed in a tubular pillar *r* provided with a vacuum-gage to indicate the exhaustion at the bottom of the mass of stuff in the bin. The channels *c*, *d* are covered with perforated tiles *e* preferably having upstanding branches to prevent ingress of liquor into the channel system. The channels may be omitted, pipes connected with exhausting-means then being disposed in the spaces between the floors *a*, *b*. (Br. Pat. 178,209. W. H. Salmon, Gravesend. June 8, 1922.)

Cholesterol — Crude cholesterol materials such as woolfat are purified by treating them with nitric acid, preferably with agitation and heating, for example, to 60 to 120 deg. C. The product is stated to vary from a hard wax-like substance to a highly viscous and elastic body and to be suitable for such technical applications as leather dressing, waterproofing, water- and acid-proof packing and joints, or as media in the preparations of decorative or anti-corrosion solutions. (Br. Pat. 179,241. F. G. Conyers and O. Reynard, Bradford, Yorkshire. June 28, 1922.)

Purifying Hydrocarbons—Hydrocarbons are purified by treatment with acid under conditions of concentration, temperature, pressure and duration such that sulphonation is avoided and the liquid polymerization products are insoluble in the acid and remain dissolved in the hydrocarbon, from which they are recovered by distillation. In the case of sulphuric acid, the concentration is always less than 60 deg. Bé., acid of 46 to 48 deg. Bé. being preferably used with heat. Phosphoric acid may also be used. For example, heavy solvent naphtha is treated with 10 per cent of phosphoric acid of density 1.70 or of sulphuric acid of 46 to 48 deg. Bé. at a temperature of 110 deg. C. for several hours. The acid is then drawn off, the solution neutralized and distilled in steam, yielding a viscous oil and a substance which may be used as a varnish. The treatment of xylene, benzene, toluene and light tar oil is also described. The process is also applicable to aliphatic hydrocarbons if these do not contain large quantities of aromatic derivatives. (Br. Pat. 179,610. J. Demant, Paris. July 5, 1922.)

Distilling Hydrocarbons—In distilling and cracking hydrocarbon oils by vaporizing the oil at about atmospheric pressure and compressing and condensing the vapors under pressure, the pressure is increased during the course of the distillation so that the heavier vapors coming off at the later stages are cracked by the heat generated by the compression and a uniform distillate is obtained. The still is supplied with oil from a vessel in which it is mixed with steam by a rotary stirrer to heat the oil to about 40 deg. C. The vapors generated in the still are withdrawn by a compressor and are passed through a condenser and receiver still under pressure. Uncondensed gases pass to the burners. When the evolution of vapor in the still ceases and the pressure falls below atmospheric, the temperature of the still is raised step by step and is maintained after each rise until evolution of vapor ceases. When the oil has reached a cracking temperature (about 300 deg. C.) superheated steam is passed into the still. The compressor is operated so as to maintain a pressure of about 125 lb. per sq.in. in the receiver until a temperature in the still reaches 300 deg. C., and the pressure in the receiving tank is raised about 25 lb. per sq.in. for each subsequent increase of 100 deg. C. in the still. (Br. Pat. 179,644. S. L. Gartlan and A. E. Gooderham, Toronto. July 5, 1922.)

Soya Bean Oil—To prepare inodorous and colorless oil and flour from soya beans, the beans, coarsely broken and freed from husk, are treated with an aqueous solution of organic acid, such as acetic acid or table vinegar, washed and dried. The oil is then expressed in known fashion, the temperature being kept too low to coagulate the albumen. The residue is ground to flour, which may be used either as food or in the manufacture of soap, washing powder, etc. (Br. Pat. 179,776. Y. Yamamoto and I. Mizusawa, Japan. July 5, 1922.)

Hydrogen and CO—In the process for producing hydrogen, carbon monoxide or a mixture of these gases by permitting steam or carbon dioxide or a mixture of the two to pass through an electric arc with sulphur vapor, as described in the parent specification, the metal sulphides are utilized directly in the electric furnace. By this means the metal formed also reacts, giving further quantities of hydrogen or carbon monoxide. (Br. Pat. 181,326; not yet accepted. Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiana. Aug. 2, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Suit Against Chemical Foundation Filed

Government Asks Return of German Patents and Charges Conspiracy to Form Dye Monopoly

THE Department of Justice filed a suit in equity on Sept. 8 in the United States District Court at Wilmington, Del., against the Chemical Foundation, Inc., charging a monopoly in dyestuffs and seeking the return to the Alien Property Custodian of all former German patents, trademarks and other rights held by this organization, of which Francis P. Garvan, former Alien Property Custodian, is president.

The government in its bill of complaint makes broad and general allegations of the existence of a dye and chemical monopoly in the United States, which was stimulated by the shutting off of these products from Germany during the war. It states that control of the industry was effected between a number of chemical corporations and chemists' societies. It names the National Aniline & Chemical Co., the General Chemical Co., the Solvay Process Co., the Semet-Solvay Process Co. and The Barrett Co., all of which in 1920 were combined into the Allied Chemical & Dye Corporation, and E. I. du Pont de Nemours & Co. Trade organizations given were the American Dyes Institute, the American Chemical Society, the Chemical Manufacturers' Association of the United States and the Textile Alliance.

Including exhibits of several hundred pages, the complaint covers more than five hundred printed pages, and it is attested to by Thomas W. Miller, Alien Property Custodian. The United States of America, by Attorney-General Daugherty, is listed as complainant. The solicitors for the government are Henry W. Anderson and Herman J. Galloway, special assistants to the Attorney-General, and William W. Wilson, general counsel for the Alien Property Custodian.

Lists the Rights Transferred

The complaint states that included among the patents acquired by the Chemical Foundation were substantially all of the enemy-owned patents of any value which had not been previously disposed of, regardless of whether they related to the objects of the Foundation, such as machines for making fringes, airplane parts, telescopes, field and spectacle glasses and turbine engines. The bill charges that some of the patents acquired by the Chemical Foundation already had been granted by the Federal Trade Commission. It states that the Alien Property Custodian at the end of the Wilson Administration had transferred to the Chemical Foundation 4,813 patents, 281 applications for patents, 876 trademarks, 492 copyrights and rights under 56 contracts relating to patents for a gross consideration of about $271,000. The complaint declares that royalties amounting to $1,152,048 had accrued to the Foundation up to June 30, 1922, and that the average income from these licenses was approximately $300,000 a year.

The government declares that the records relating to these transactions were in the possession of Alien Property Custodian Garvan and his agents, who were also officers of or connected with the Chemical Foundation until the change in Administration; that many of the records were removed to the offices of the Chemical Foundation and that many of the facts stated in the bill only recently have come to the knowledge of the present Administration.

What the Government Demands

It declares that the Foundation has now pending many suits against the government resulting from patent licenses previously issued by the Federal Trade Commission. It asks that these suits be enjoined.

A return of all properties, the removal of any cloud upon the titles caused by their sale, and an accounting and repayment of all income and profits realized by the Chemical Foundation are demanded.

Believe Soviet Activities Boost Caustic Shipments to Germany

Heavy Russian purchases of caustic soda in Germany are believed to explain, in part at least, the large movement of this commodity to Germany. Since the bulk of the movement is to Hamburg it would seem that much of the American product is being reconsigned to Russian points. If the shipments were intended for the German chemical plants, the natural destination would be Bremen, it is declared. There is reason to believe that the Russians are using this material in the manufacture of picric acid. Some anxiety is being caused by this and other evidences that the Soviet authorities are launching heavily into the manufacture of explosives.

Dye Embargo Back in the Tariff Bill

The dye and chemical control act, the so-called embargo, will be extended one year and even a second year if the President deems this necessary to protect the development of the domestic industry, according to the terms of the conference report on the Fordney-McCumber tariff bill. The conferees also agreed upon rates for coal-tar products of 50 per cent ad valorem and 7 cents per pound on intermediates and 60 per cent ad valorem and 7 cents per pound on finished dyes and chemicals, the ad valorem rates being based on American valuation.

The ad valorem rates represent an increase from 30 to 50 on intermediates and from 35 to 60 on the finished product over the House rates and are practically double the rates recommended by the Senate Finance Committee, for, while the same figures are used, the valuation basis has been changed from foreign to American. The rates are lower than those adopted by the Senate in the Bursum amendment, which carried 75 per cent plus 10½ cents per pound on intermediates and 90 per cent plus 10½ cents per pound on the finished product, the ad valorem being on American valuation.

Peril for U. S. Tariff Commission Seen in Senate Tariff Bill

Probable impairment of the usefulness of the United States Tariff Commission is seen by the Chamber of Commerce of the United States in the event of enactment of the tariff bill as passed by the Senate authorizing the commission to adjust flexible customs rates. This view was expressed in a letter sent to members of Congress by Julius H. Barnes, president of the chamber, in which it is urged that a separate governmental body be created to adjust rates.

Urges Creation of Another Commission

In the opinion of Mr. Barnes, "the field of work to be covered in applying adjustable rates is broad enough and sufficiently varied to warrant two separate bodies—the present Tariff Commission with its statisticians, research workers and field agents to continue the highly important work of investigating and advising, a new Tariff Adjustment Board to hear evidence and to render decisions within limits set by Congress.

"If Congress adds new duties and quasi-judicial functions to the present duties of the Tariff Commission," he writes, "it will endanger the usefulness of that body."

New Bauxite Development in Tennessee

It is reported in Birmingham, Ala., that a syndicate of Chattanooga business men have organized a company for the purpose of developing large holdings of bauxite ores on Missionary Ridge. It is stated that this concern proposes building a smelter, in addition to mining the ores, for the purpose of turning the ores into billets.

The company is said to have acquired at least 1,000 acres of these ore lands; and engineering reports on the land acquired are to the effect that they are very rich in the ore from which aluminum is made.

The initial capital of the syndicate is to be $1,000,000, and a large percentage of the funds have been pledged; in fact sufficient to assure the opening of the mines and the erection of the first unit of the smelter, according to reports.

The developers of this new bauxite ore property point with enthusiasm to the fact that the electric power available is sufficient for any operations they may contemplate; and will make an effort to get their operations going in time to be with the vanguard in the new rumored developments in the automobile motor field.

Oil Consumption in July Sets Record

Consumption of crude petroleum in July was the highest on record for any month, having increased more than 51,000 bbl. as compared with June, while the daily average production decreased 15,633 bbl., the Geological Survey announces in its monthly report.

Domestic production in July aggregated 46,593,000 bbl., an average of 1,503,000 daily, compared with 45,559,000 bbl., an average of 1,518,633, in June.

Imports were estimated at 11,308,000 bbl., an average of 364,773 daily, compared with 12,182,000, an average of 406,062 bbl. daily.

Stocks held July 31 aggregated 261,478,000 bbl., or a supply of 158 days, compared with 255,817,000, or 159 days' supply so held on June 30.

Estimated consumption of domestic and imported petroleum was 51,387,000 bbl., an average of 1,657,645 daily, compared with 48,192,000, an average of 1,606,400 daily, in June.

Imperial Oil Will Build Refinery at Calgary, Canada

The Imperial Oil Co. has decided to build a large refinery at Calgary. C. O. Stillman, president, and A. M. McQueen, vice-president of the company, were in Calgary recently, looking over sites and making negotiations with the Mayor and City Commissioners for certain concessions in the event of a refinery being erected. At a meeting of the directors, held Aug. 18, the building of the refinery was approved, and the Mayor of Calgary was notified.

The refinery will be built on waste land in southeast Calgary.

Industrial Engineers to Meet in New York

Ninth National Convention of the Society to Discuss Economics of Industry

A number of subjects of general interest are included in the final program of the meeting of the Society of Industrial Engineers, which is scheduled for Oct. 18 to 20 at the Hotel McAlpin in New York. The general scheme of the discussion will be "Economics of Industry," and a number of well-known engineers and executives will contribute their ideas to the discussions of various phases of this topic. Sectional meetings for managing executives, production managers, sales managers, industrial relations directors, accountants and educators are included in the program. The international committee for the elimination of unnecessary fatigue will hold an open meeting.

A special feature will be an exhibition of factory and office equipment designed to save labor and reduce fatigue. The exhibition will be held in the winter garden adjoining the ball room in which the principal meetings will be held.

Wednesday's Program

The opening session on Wednesday afternoon, Oct. 18, will be addressed by Joseph W. Roe, president of the society, on the subject "The Relation of Economics to Industry." A. J. Lutterbach of the Palmolive Co., Milwaukee, Wis., will address the society the same evening on "The Budget and the Financial Forecast." Another paper of general interest at this session will be presented by L. W. Wallace, secretary of the Federated American Engineering Societies, on "The Importance of the Elimination of Waste to the Economic Structure."

Thursday Afternoon Meeting

Two important economic factors will be considered at the Thursday afternoon meeting, when symposiums are scheduled on the following topics: "How Can We Reduce Production Costs?" and "How Can We Keep the Worker Contented?" The annual banquet of the society is scheduled for Thursday evening, at which D. R. Dewey of the Massachusetts Institute of Technology will address the gathering on "The Relation of the Economist to Business" and Francis H. Sisson of the Guaranty Trust Company of New York will speak on "Finance and Industrial Economics."

Meetings on Friday

Friday morning will be given over to the sectional meetings enumerated above, at which a number of well-known speakers will discuss pertinent topics. The closing sessions on Friday afternoon will include talks by Ernest F. Dubrul, general manager of the National Machine Tool Builders' Association, on the "Economic Aspect of Production" and by A. J. Todd, director of labor, B. Kuppenheimer & Co., on "The Industrial Age."

Dye Investigation to Be Resumed Next Winter

A partial report from the special dye investigation committee of the Senate will be submitted before the present session ends, according to Senator Shortridge of California, chairman of the special committee.

Senator Shortridge declined to indicate the nature of the report. His personal attitude, however, was indicated to some extent by his statement on the floor of the Senate in July, when the dye embargo of the tariff bill was defeated, at which time, in defending the proposed embargo, he stated that not only had the investigation failed to disclose a monopoly of the dye and chemical industry of the country but that it had established the fact of "active competition."

The special committee held hearings for several weeks last spring before adjourning indefinitely. It is expected the committee will resume hearings next winter and conclude its work by clearing up a few points which were not touched in the testimony last spring.

Delay in drafting the partial report is due to absence of some members of the committee, according to Senator Shortridge. He stated that he expects to submit the report after the Dyer anti-lynching bill has been disposed of. This bill has been set as the last of the outstanding measures to be taken up at this session of Congress, according to the program announced by the Republican steering committee.

Evening Chemistry Courses Offered by City College of N. Y.

A series of evening courses in chemistry is announced by the College of the City of New York. The project has been arranged by the Evening Session Chemical Society as an opportunity for those engaged during the day to take up special subjects or to lay the foundation for a degree in chemistry. Besides the B. S. and Ch. E. degrees, a special departmental certificate is given to students who desire chemical knowledge only. To receive this certificate the student must complete the courses with an average of 80 and make a satisfactory report on some research problem. Thus the certificate indicates that the holder has a knowledge of the main branches of chemistry, a very good scholarship rating and some practice in research.

In addition to the various branches of chemistry usual in college courses the night sessions this fall will include two courses of interest to graduate and special students. Both will be under the direction of F. E. Breithut. Chemistry 159 concerns food inspection and analysis and Dr. Breithut plans to include lectures and excursions in cooperation with the Department of Health of New York.

Registration for the fall term starts Sept. 18. Further information may be obtained by writing to the Evening Session Office, College of the City of New York, Convent Ave. and 140th St.

Manufacturers' Attorney Attacks Dyestuff Duties

George Demming of Philadelphia Says Excessive Duties Prohibit Competition and Tend to Form Monopoly

"EXTORTIONATE" is the term applied to the present dye tariff rates by George Demming, attorney for a large group of Philadelphia, eastern Pennsylvania, New Jersey, Delaware and Maryland manufacturers, who will shortly appear before the House and Senate conferees in Washington to wage a vigorous fight for the reduction of the present duties.

The manufacturers who were opposed to the dye embargo are even more strongly opposed to the present tariff schedule, according to Mr. Demming, who declared that the duties were worse than the former embargo. Mr. Demming stated that Senator Smoot, who is leading the fight on the floor of the Senate for a lower dye tariff, made the following statement, which many manufacturers do not understand:

"For any foreign manufacturers of dyes to get by these rates, he would have to bring dyes to this country, give them away free of charge to the consumer and then pay the consumer money for the privilege of receiving the gift." How these words of Senator Smoot work out on a practical basis is explained by Mr. Demming as follows:

How It Works Out

"We will assume that a domestic dye, similar in quality to a foreign dye selling at 20c. a lb. abroad, is quoted in the American market for 80c. The American manufacturer, finding out that the domestic dye will not do exactly what the foreign dye does, desires to get the foreign product. He pays 20c. a lb. for the foreign product, approximately 10c. a lb. for transportation, insurance and overhead, and the dye is delivered here at a cost of 30c. Then the costs begin to mount. First the importer has to pay an ad valorem duty of 90 per cent base on the American valuation plan, which would be 90 per cent of 80c., the value of the similar American product, or a charge of 72c. per lb. Then, in addition, he pays 10½c. specific duty, or a total of 82½c. duty. Adding to this the original cost of the dye, plus transportation expenses, etc., we find that it will cost the American importer $1.12½ to get the article he wants. At this price the foreign article is naturally unable to compete with the domestic product. Thus Senator Smoot's contention is correct, and should the foreign manufacturer wish to compete with the American product, he would not only have to donate the dye, transportation and other expenses but would also have to give the importer 2½c. a lb. for taking the material."

More Than 100 Per Cent Protection

"In other words," said Mr. Demming, "the ad valorem and specific duties amount to more than 100 per cent of the value of the article under the American valuation plan, and when you protect articles to the extent of more than 100 per cent you are entering the field of extortion."

Mr. Demming asserted that in Pennsylvania manufacturers have found that the dyes, which are an absolute essential as one of their raw materials, are protected at a higher figure than that afforded their own finished products. The ordinary business man is said to want to know why the raw materials are offered this higher degree of protection than the finished manufactured product, as dyed articles made abroad, such as are manufactured in this district, are not protected by any such duties.

International Exposition and Congress on Liquid Fuel

French Government Departments Cooperating With Société de Chimie Industrielle

Final announcement of the International Exposition and Congress on liquid fuel is made by the Société de Chimie Industrielle and a cordial invitation to American representatives to attend is extended by Ambassador Jusserand. The congress will be held in Paris Oct. 4 to 15 and will be divided into two parts. During the first part of the congress discussion will be centered on the terminology of petroleum products and methods of analysis. These topics will be examined from three points of view—scientific, industrial and legislative—by three groups of specialists competent in the respective branches. The purpose of this study will be to furnish for each term the exact definition corresponding to each country and the exact description of the method of analysis employed. The congress has no intention of attempting to set international standards, but rather clearly and precisely to establish comparative tabulations, so that the present usages in all countries regarding terminology and methods may be perfectly understood by all concerned.

Following this part of the program the congress will divide into six sections in which will be brought together all the important developments and new researches in the fields of various liquid fuels. The subjects to be considered in these discussions include petroleum, shales, lignite and peat, tars and benzene, alcohol, and vegetable oils.

Arrangements for the congress have been made in co-operation with the Ministers of Commerce, Agriculture, Colonies, Public Works and Aëronautics of the French Government. Representatives of these departments will be present and participate in the discussion.

Arthur W. Thomas, 50 E. 41st St., New York City, is the secretary of the Société and is prepared to furnish further particulars to all who may be interested.

Extension of Control Act Asked by Equipment Manufacturers

Petition Sent to Senate Finance Committee Signed by One Hundred Manufacturers of Chemical Equipment

The Chemical Equipment Association through J. George Lehman, its chairman, has submitted to Senator McCumber, chairman of the Finance Committee, a petition urging favorable action on the amendment extending the dye and chemical control act, in accordance with the report and vote of the Finance Committee. In his letter of transmittal, Mr. Lehman pointed out that the Chemical Equipment Association represents the manufacturers of chemical equipment in the United States and that during the war every member of the association rendered every possible aid to the government. This resulted in expanded or relocated plants and personnel, both of which are now largely unemployed due to the uncertainty as to whether the industry will be accorded adequate protection. It is maintained that adequate protection for the chemical industry will not only assist that vital branch of our productive interests but will simultaneously assist some hundreds of co-ordinate lines to continue the advancement made in recent years, to maintain reasonable financial stability and to give wider employment to men now seeking work. The petition as submitted to Senator McCumber follows:

> The undersigned, whose business is specifically that of supplying equipment necessary to the American chemical manufacturer and industry, and believing that their close contact with the latter provides an intimate knowledge of their needs, respectfully submit for your consideration:
>
> 1. That the chemical manufacturer requires an endless variety and enormous volume of special equipment, the production of which in this country has progressed in step with the developing needs of the chemical manufacturer;
> 2. That the chemical equipment industry before the war was very small as compared with today;
> 3. That this equipment field represents millions of capital and thousands of employees, both now unemployed to a great extent, and, in our judgment, certain to remain so unemployed unless the American chemical industry is properly safeguarded and maintained in a flourishing condition;
> 4. Therefore, we respectfully urge that you not only support personally all just provisions for the welfare of our chemical and co-ordinate fields, but that you use your good judgment and effort in bringing your colleagues to do likewise, by voting for the amendment extending the dye and chemical control act, in accordance with the report and vote of the Finance Committee.

The petition was signed by over ninety manufacturers of all types of chemical equipment in every section of the country.

Headquarters for Chemical Engineers at Exposition

Members of the American Institute of Chemical Engineers are cordially invited to make use of *Chem. & Met.'s* booth as headquarters at the Chemical Exposition. A register will be provided and every facility afforded for bringing members of the Institute together.

Standard Oil of N. J. Says Mexican Oil Fields Are Near Exhaustion

Nation-Wide Search Must Be Made for New Fields—Future of Mexico's Oil Industry Largely Dependent on Government's Attitude

THE first era of the Mexican oil industry is drawing to a close, according to *The Lamp*, the house organ of the Standard Oil Co. of New Jersey, which gives a comprehensive survey of the past and present situation in the second largest producing country.

The production of petroleum in Mexico dates from about the year 1901, but it was not until 1911 that yield assumed such proportions that a surplus over domestic consumption was available for export. Only during the past few years has Mexican oil become a real factor in the world's markets and an important source of revenue to the government and people of Mexico.

Producing operations up to the present time have been largely confined to lands owned in fee or leased from individuals in two districts lying within the area bounded on the north by the Tamesi River; the Tuxpam River on the south; the Gulf of Mexico on the east; and on the west by an irregular line extending from the mouth of the Vinasco River through the Otontepec Mountains to the Panuco River, thence to the Tamesi. Although this area contains something like 2,470,000 acres, production has been found concentrated only in two producing districts—the Panuco field, producing very heavy, viscous oil, and the southern field, producing a somewhat lighter gravity oil.

Situation Critical

In both the producing fields above mentioned, exhaustion of oil resources has reached such a point that the exploitation of at least two-thirds of the estimated 25,000 acres of the producing area have been abandoned. In the Panuco, or heavy oil fields, where once 125,000 bbl. per day were produced, the average is now only about 100,000. In the southern field Mexico at one time produced as much as 500,000 bbl. of light crude oil in a day. Within the last few weeks this has been reduced to less than 300,000 and is still declining rapidly.

Explorations of the past 20 years within this vast area have developed only the two producing districts named, which together contain approximately 25,000 acres, or about 1 per cent of the area explored. It is estimated that the investment in the exploration and exploitation of Mexican oil has been not less than one billion pesos, or $500,000,000 United States currency. These figures do not take into consideration the cost of tanker fleets and foreign storage, manufacturing plants and other facilities created for the handling of Mexican oil.

The present situation is critical because the progressive exhaustion of the production has not been compensated by the exploration of new territory and the discovery and opening up of new fields. The oil industry will have no future in Mexico unless an intensive effort to find new fields of production be undertaken and successfully prosecuted. The areas to be explored are more remote from the ports of shipment than those now producing, and the necessary development work can be carried through only by expenditure of a vast amount of new capital.

It is essential to the permanency of the petroleum industry, as known fields begin to be exhausted, that reserves for the future be discovered by the extension of operations to other prospective areas.

The conditions and circumstances which have interfered with the carrying out of this established practice in Mexico, including those conditions which have prevailed to deprive capital of the fundamental and essential insurance which it must have as to its investments and the conduct of its operations, have largely grown out of the unsettled political situation that has prevailed in Mexico for the greater part of the last 12 years.

Unfortunately both for the welfare of Mexico and of the petroleum industry, the consequences of this situation must be suffered now and in the months near at hand. The future of the oil industry in Mexico rests primarily in the hands of the government.

Paint Company Must Stop Rebate Sales Scheme

The De Soto Paint Manufacturing Co., manufacturer and distributor of paints and similar products at Memphis, Tenn., is required by recent order of the Federal Trade Commission to discontinue certain competitive methods which the commission found upon inquiry to have been followed by the company.

The commission's order is directed to respondent's practice of making an arbitrary selection from among purchasers of certain of its products, to whom rebates or bonuses are paid. Under the terms of the order, the De Soto company is required to refrain from discriminating in net selling prices by any method between purchasers of the same grade, quality and quantity of commodities, upon the basis of a classification of its customers as "professional or contracting painters" or other similar classification.

The trial of the case developed that the De Soto company gave to professional or contracting painters a certificate for each gallon of paint purchased, such certificate being redeemable at the rate of 20 cents for each gallon of colored paint and 10 cents for each gallon of white paint purchased. These certificates were not given to purchasers other than professional painters.

Societies Would Aid Power Commission

Federated American Engineering Societies Move to Improve Personnel

The work of the Federal Power Commission cannot be organized on an effective basis until the commission is given the right to employ its own personnel. The Federated American Engineering Societies is trying to obtain the necessary legislation. The Secretary of War has written to the Federated Societies pointing out the difficulties of the existing situation. An extract from Secretary Weeks' letter is as follows:

> The commission is seriously handicapped in the administration of the act on account of inability to employ its own personnel. It has had placed upon it the greatest task with respect to water powers the government has ever had, at a time when the utilization of water power is more necessary than ever before. The act made a definite pronouncement of a national policy in water-power development. It created a commission to carry out that policy, but it gave it no means to do so. The commission has been obliged to depend exclusively upon such assignments from the several departments as these departments were willing to spare. The departments have had their own forces cut to a point where they are unable to perform either in Washington or in the field the work required of the commission under the act; and even if they had the numbers and the funds to pay them they do not have employees with a training or an experience required for the performance of certain of the duties of the commission. As a necessary consequence the commission has been forced to omit altogether action upon important matters which the act requires of it. Furthermore, with no personnel of its own and with no control over the personnel of the departments engaged upon its work (except for the small number directly assigned to its Washington office) it is not possible to organize the work on an effective basis, or to make the most economical use of the personnel actually engaged on the commission's work or of the funds actually expended for such purposes.

In its first annual report the commission said:

"What is seriously needed in the interest of adequate administration of the act is a small organization of trained and experienced men capable of meeting intelligently the important and perplexing engineering and economic problems which are constantly arising and upon the correct solution of which will depend the value of the legislation and, in no small degree, the future of the electric power industry."

Nothing has happened since to alter the situation.

Vanderbilt University Robbed of Platinum Laboratory Apparatus

Over two thousand dollars' worth of platinum laboratory apparatus was stolen from Vanderbilt University, at Nashville, Tenn., some time between Aug. 1 and 8. The missing apparatus included six crucibles, a milk dish, two combustion boats, two evaporating dishes and a new platinum combustion tube. The university authorities are making determined efforts to prevent the thief from disposing of the booty and have broadcasted a request for information that might lead to its recovery.

The Airplane and the Boll Weevil

Calcium Arsenate to Be Spread Over Cotton Fields From the Air

The use of much larger quantities of calcium arsenate in the control of the cotton boll weevil is expected to result from the very successful experiments in dusting cotton fields by airplane. The experiments have been conducted under the direction of B. R. Coad, in charge of the laboratory of the Department of Agriculture at Tallulah, La. In a special report made by Mr. Coad and read on the floor of the House of Representatives, it was shown that with crude apparatus it was possible to poison 20 acres of cotton per hour in a much more thorough manner than ever had been attained by the equipment operated on the ground.

The air blast from the propeller of the plane disseminates the particles of the material in such a way that they filter down through the air and settle regularly over the entire plant. The amount of material needed per acre is reduced one-half.

The success of these experiments has been so decided that community poisoning is to be undertaken at once in many districts. As a result there will be much wider application of the poison and much more effectual control. In addition to the better distribution of the material when applied from the air, the whole region will be covered, thereby preventing migrations of the weevil from unpoisoned tracts, as is the case at present.

Mr. Coad in his report points out that these experiments have an important bearing on the control of insect pests which attack any field crop. Airplane dusting can be done so rapidly and save so much labor that its cost will be a very small percentage of the present cost of poisoning, particularly when the hopper and fan equipment being used on the airplane have been perfected and enlarged.

Prof. Roe of New York University to Aid Eyesight Conservationists

Election of several engineers and educators to the board of councilors of the Eyesight Conservation Council of America is announced from the headquarters of the council in New York by Guy A. Henry, general director. Engineers chosen include Prof. Joseph E. Roe, head of the department of industrial engineering in New York University, and Dr. F. C. Caldwell, professor of electrical engineering in Ohio State University.

Professor Roe is a member of the executive board of the American Engineering Council of the Federated American Engineering Societies and president of the Society of Industrial Engineers. Professor Caldwell is chairman of the committee on education of the Illuminating Engineering Society. L. W. Wallace, executive secretary of the Federated American Engineering Societies, is president of the Eyesight Conservation Council, which plans further to enlist the co-operation of the engineering profession.

Professor Roe described eye conservation, which is to be intensively carried on in the classrooms and workshops of the nation, as an important public service made possible largely through the disclosures by the Hoover Committee on the Elimination of Waste in Industry. Enormous losses, Professor Roe said, were being sustained by the nation through defective eyesight. Surveys in industrial centers and in city and rural schools are showing that economic and physical damage is being caused simply through failure of parents, teachers and factory managers to correct faults which can be remedied.

Additional Plans for Detroit Convention of Steel Treaters

In addition to the plans announced in *Chem. & Met.* for the convention of the American Society for Steel Treating and the American Drop Forging Institute, to be held in the General Motors Building at Detroit from Oct. 2 to 7, other happenings of interest have been arranged for the same period.

H. N. Taylor, president of the N. & G. Taylor Co. and president for the past 8 years of the Drop Forge Supply Association, has made arrangements for holding a meeting of the members of his association at 12:30 p.m. on Tuesday, Oct. 3, in the General Motors Building.

F. M. Waring of the Pennsylvania R.R., chairman of Committee A-1 on Steel of the American Society for Testing Materials, has called a meeting of his full committee to be held at Detroit on Oct. 5 and 6, in the Hotel Statler.

On Thursday, Oct. 5, a bronze tablet will be unveiled on the walls of the Wyandotte Public Library to the memory of those pioneers who in 1864 erected the first commercially successful bessemer steel converter on that site. This tablet is the gift of the Detroit Chapter of the American Society for Steel Treating and marks the first public recognition of the achievements of William Kelly, who made his first bessemer steel in 1847 and patented his process in 1856.

Announcement will be made during the convention of the American Society for Steel Treating of the rules governing the award of the Henry Marion Howe Medal, a gold medal to be given annually to the author of the paper considered of highest merit on any subject within the field covered by the society and commemorative of the distinguished services rendered by the late Dr. Howe.

A.C.S. Council Announces Prize for American Chemists

Announcement of a $25,000 prize, to be awarded annually to the American who makes the most notable contribution to chemical science, was one of the outstanding features of the first meeting of the council of the American Chemical Society on Sept. 4 at Pittsburgh.

American Mining Congress to Organize Southern Division

Active Support to Be Given to Plans to Push the Muscle Shoals Power Project to Completion

Active support for the completion of the Muscle Shoals, Ala., power project is being given by the American Mining Congress, which will hold a convention at Chattanooga, Tenn., on Sept. 29, for the purpose of organizing a Southern division of the organization. The Governors of the Southern States, mining operators and others have been invited to assist in the movement, which, it is claimed, will result in the creation of a great Southern mineral empire.

Development of Cheap Power and Transportation Essential

"The most important thing in the South today is the development of cheap power and transportation," said James F. Callbreath of Washington, D. C., secretary of the American Mining Congress. "With this in view, the American Mining Congress proposes to consolidate its existing state chapters in the South into a Southern division, thus placing the entire organization of the American Mining Congress behind the completion of the Muscle Shoals project. The development of the Muscle Shoals project is essential, first, for transportation; second, for cheap power; and third, because its completion combined with the proximity of the great mineral resources of the South to the natural markets and superior supply of labor creates the possibilities of a great Southern mineral empire, which can compete with the products of any other region.

Opportunities of the South

"Many mining operators in the South have never awakened to the possibility of utilizing the efficiency of large operations analogous to the development of the porphyry coppers of the West," continued Mr. Callbreath. "The widely diversified and disseminated deposits of graphite, phosphate, manganese, barytes, pyrites and other minerals in the Southern States and their successful marketing call for collective thought and co-operative action. Cheap power is a prerequisite to successful mining operations. Without highly developed transportation, successful marketing cannot be attained. The mining industry is an essential factor to national prosperity. The constructive work of the American Mining Congress in behalf of the mining industry during the past 25 years entitles it to the heartiest support, complete indorsement and active co-operation of every man interested in the industrial development of the South."

Mr. Callbreath will outline the scope and purpose of the new organization in an address before the Chattanooga meeting, which will be held at the Hotel Patten and for which preliminary arrangements are being made by Dr. Henry Mace Payne, consulting engineer of the American Mining Congress.

Water Pollution Bill Passed

Quick Action on Frelinghuysen Bill to Prohibit Discharge of Oil

The Senate on Aug. 31 passed, without debate, a bill to prevent pollution of navigable waters by the discharge of oil. The measure was introduced only the preceding day by Senator Frelinghuysen of New Jersey to replace in more simple form the several pending bills on the same subject. It was reported favorably by Senator Willis, for the Committee on Commerce, with a brief report calling attention to the indorsement of the general plan by Secretary of War Weeks and Major-General Lansing H. Beach, chief of engineers, and was adopted with only a perfecting amendment offered by Senator Lenroot of Wisconsin, being disposed of quickly between the vote on the bill for adjusted compensation for former service men and debate on one of the administration coal bills.

The measure makes it unlawful to discharge oil—including fuel oil, smudge or refuse—upon, into or under navigable waters of the United States from any vessel, excepting for the purpose of smoothing the sea in case of emergency or under such regulations as may be prescribed by the Secretary of War in such quantities as shall not be deleterious to health or fish or dangerous to property. A fine of $2,500 for violation is provided and clearance papers may be denied until the fine is paid. The act does not become fully effective until 3 months after its passage and may be suspended in time of war.

The brief report accompanying the bill set forth a letter from General Beach calling attention to the lack of legislation to control oil pollution and its need, together with excerpts of hearings on previous bills calling attention to the fire hazard and destruction of fish and vegetable life by oil on waters.

Tons of Picric Acid to Be Distributed to Farmers

The Bureau of Public Roads, United States Department of Agriculture, is making plans to release, for shipment to farmers this fall, millions of pounds of picric acid for agricultural explosive purposes, such as clearing lands of stumps, etc.

This distribution of high-grade agricultural explosives to farmers by the government is to be without cost except 7 cents per pound for drying and cartridging expense plus the cost of the freight. Originally about 12,000,000 lb. of the picric acid was available as war surplus. A considerable amount was distributed to the states for road-building purpises by the government and there now remains approximately 5,000,000 lb. to be distributed this fall. The Bureau of Public Roads urges farmers in all sections of the country who can use this explosive to apply now for it, so that the fall shipping schedules may be made up for the states. Some of it is located at Fort Wingate, New Mexico, and an additional supply, for shipment to Eastern points, is located at Edgewood Arsenal, Maryland.

Picric acid is classed among the safest of explosives while at the same time being powerful, and for these reasons, if for no other, is ideal for blasting purposes. It also has advantages over commercial explosives, among them being that it keeps indefinitely and is not affected by heat or cold. Because of its greater cost of manufacture, it is not a competitor with commercial dynamite. It is being distributed for the purpose of increasing interest and activity in land clearing.

The Minnesota State Agricultural College reports: "We feel that picric acid has been a great benefit to the state and has done a great deal to stimulate land clearing. All reports are to the effect that its use has been highly satisfactory. The 744,000 lb. allotted to Minnesota last year was distributed to 3,511 farmers, averaging 222 lb. to the farmer. We estimate this will clear 35,000 acres of land and has made a saving of over $70,000 for the farmers of the state."

House Sidetracks Muscle Shoals

The President has authorized the transfer of certain river and harbor funds which makes available an additional $600,000 to apply on the work at Muscle Shoals. This amount insures the maximum amount of work which can be done on the project at this time and adequately bridges the period prior to Oct. 1, when the $7,500,000 appropriation becomes available.

The struggle in the House to obtain consideration of the Ford offer continues. Representative Garrett of Tennessee, the acting minority leader, forced the majority to abandon its plan for 3-day recesses. He is forcing roll calls on adjournment and resorting to all parliamentary tactics to speed the disposition of other business before the House with the idea that the majority then will be compelled to proceed to the consideration of the Ford offer.

Representative Mondell of Wyoming, the majority leader, states that he has no disposition to block the consideration of the matter, but contends that the legislative situation is such that it would be perfectly idle to call up the matter at this time.

It is possible that the House may take up Ford offer at this session, but the probabilities strongly favor the deferring of such action until the December session.

I.C.C. Rules on Shipment of Linseed-Oil Meal

The Interstate Commerce Commission has ruled that rates charged on carload shipments of linseed-oil meal from Undercliff, N. J., to Chicago, Ill., and North Hammond, Ind., are not unreasonable except as to shipments moved over the New York Central.

Personal

ARTHUR W. AMBROSE has been selected to succeed E. A. Holbrook as assistant director of the U. S. Bureau of Mines. Mr. Ambrose has been in the service of the bureau since 1917, during which time he has risen through the various grades from petroleum technologist to chief of the petroleum division of the bureau. His appointment as assistant director is an indication of the increasing importance of the bureau's petoleum work. F. B. TOUGH, who has been serving the bureau as chief supervisor of oil and gas leases, will succeed Mr. Ambrose as chief petroleum technologist. F. J. BAILEY, the assistant to the director, under a rearrangement of the work will take over a portion of the duties formerly assigned to the assistant director so as to permit Mr. Ambrose to give a portion of his time to the petroleum work. Mr. Ambrose comes originally from Lodi, Calif. His technical education was obtained at Stanford University, where he received his mining engineer's degree. Prior to his employment by the Bureau of Mines in 1917 he was in the service of the Dutch Shell and other petroleum companies. Just prior to his appointment as chief petroleum technologist, 2 years ago, he was superintendent of the petroleum experiment station at Bartelsville, Okla. Mr. Bailey is a graduate of Middlebury College, Vermont, and a graduate in law from George Washington University. He has been with the Bureau of Mines since its organization in 1910. As assistant to the director he has already had charge of a large part of the work including the Mine Safety Service.

ARDEN E. HARDGROVE, city chemist at the Akron Municipal University, Akron, Ohio, in charge of city tests, has been appointed permanent superintendent of the Akron City Hospital, succeeding Prof. Charles Bulger. He assumed his duties on Sept. 1.

Dr. KUNO B. HEBERLEIN has returned to New York after a 6 months' business trip through Europe.

GUY C. HOWARD, chemical engineer, has opened an office at 767 Stuart Building, Seattle, Wash., for consultation, investigations for industrial and financial purposes, plant design and technical supervision.

ERIC R. JETTE, who recently completed his work for the Ph.D. in Columbia University, has sailed for a year of study in Stockholm. He has an American-Scandinavian Fellowship for the year 1922-23.

J. F. SMITH has been appointed head of the research and information service of the Commercial Solvents Corporation, Terre Haute, Ind. He was formerly connected with the research department at the Buffalo, N. Y., plant of the American Aniline & Chemical Co.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Marketing Chemical Apparatus and Supplies

Reputable Manufacturers Are Facing a Serious Situation Growing Out of the Competition of Inferior, Low-Priced Goods of Both Foreign and Domestic Origin

By S. L. Redman
Central Scientific Co.

THE PAST 7 years has seen a marked change in the marketing of laboratory supplies. Prior to that time, materials were largely imported, sources were not well known and the sale of supplies was largely limited to a few firms of established reputation which held themselves strictly responsible for the quality of the products handled by them. The publicity given to chemical industry during the war, together with the ease of locating American sources of supply, led to the entrance of a number of new firms into this field, many with limited capital, limited knowledge of the business and a desire to reap quick rewards rather than to build up an institution for permanence. Having no reputation to hazard, no technical knowledge of apparatus manufacture and being desirous of obtaining goods at low costs in order to compete with established firms, some of these new dealers began to seek new sources for their supplies. The resumption of importations in 1920 favored this desire and has led to a flood of foreign apparatus being thrown on the market at low prices but of questionable quality.

This situation would have been impossible in the days when the laboratory man selected his own supplies or specified known brands or sources. The growth of the purchasing agent system, however, spreading like wildfire throughout both educational and commercial institutions, has helped to foster this condition. The purchasing agent is not always a technical man and is sometimes engaged for the purpose of making his concern's dollars stretch as far as possible. To this sort of man a burette is a burette, to be bought from the lowest bidder, and he does not care to restrict the number of bidders.

Is a Burette Just a Burette?

As a result of this situation the dealer with a reputation based on quality and service is seriously facing this dilemma: Is it necessary for him to lower his quality and skimp his service in order to secure his share of the competitive business, or can he find enough discriminating buyers to supply him with a sufficient volume of business to maintain his organization?

As an illustration of the possibility for a large difference in the price of what—to the purchasing agent—is a standard article to be bought from the lowest bidder, take the manufacture of a burette. The steps in the manufacture of a cheap and a good burette may be summarized as follows:

Cheap	Good
1. Use any stock tubing.	1. Select tubing free from striations and air bubbles.
2. Caliper only at one place for approximate diameter.	2. Caliper from end to end for uniformity of diameter.
3. Omit.	3. Check internal diameter to see that the length for the rated capacity is sufficient to bring the tenth c.c. marks at least 1 mm. apart.
4. Draw down one end and make tip or attach cheap stopcock.	4. Draw down one end and make tip or build stopcock on end or attach high-grade stopcock.
5. Put lip on other end.	5. Put lip on other end.
6. Anneal joint over flame.	6. Bake in annealing oven with pyrometer to indicate maximum temperature for 24 hours with gradual heating and cooling.
7. Select arbitrary 50-c.c. mark and point off 0 mark by rapidly running in 50-c.c. measured with another burette used as standard.	7. Carefully clean burette. Select arbitary 50-c.c. mark and point off every 5-c.c. by carefully running in portions from a certified burette, allowing full time for draining.
8. Graduate space from 0 to 50 in 500 equal linear divisions.	8. Graduate space between each two 5-c.c. marks in 50 equal linear divisions, resetting machine for each interval.
9. Wax and etch.	9. Wax and etch.
10. Melt off wax and dry.	10. Melt off wax, fill etched marks, dry and polish.
11. Omit.	11. Inspect for defective etching.
12. Wrap in paper and put in stock.	12. Wrap in paper and pack in separate carton to go in stock.

Is a burette just a burette?

How to meet this situation, which is bringing disrepute upon the entire apparatus business, is a serious problem. No reputable dealer desires to lower the quality of his merchandise, and yet his chief reward for furnishing better goods and rendering a more complete service to the laboratory man is the accusation of "profiteering." It is unfortunate that those institutions which "gambled" on the chance of securing a bargain from some "bootlegging" apparatus dealer and have been unmercifully cheated as a result do not make public their experience for the benefit of laboratory men in general. There are enough new "gamblers" each year to maintain a large number of such concerns on a very profitable basis, especially so since they are not put to the expense of developing new apparatus, or even issuing a catalog.

The best remedy in sight is apparently a long persistent campaign of education with a view to conveying to the laboratory man as much detailed information as possible about the manufacture of apparatus so that he may be able readily to detect by a brief inspection or examination fundamental

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	146.67
Last week	150.60
September, 1921	147
September, 1920	267
April, 1918 (high)	286
April, 1921 (low)	140

Not since January, 1922, has this index number reached the low level of the present report. This decline is due almost entirely to the low price of cottonseed oil, one of the most important, statistically, of the 25 commodities included in the compilation.

differences in quality of material, workmanship, finish and performance. This is a painfully slow process and the results may not justify the expense. In the long run it is believed that the situation will cure itself, and that after several sad experiences the laboratory worker may not only convince himself, but also his purchasing agent, that it is an axiom in competitive merchandising that you generally get what you pay for.

Chicago, Ill.

Production, Consumption and Prices in the Naval Stores Industry

Turpentine

More than 97 per cent of the spirits of turpentine produced in this country is from gum turpentine, the remainder from wood. Production in 1914 amounted to 27,648,939 gal., valued at $10,740,327. In 1919 the Census reported that 1,214 establishments produced 19,271,000 gal. of spirits of turpentine, valued at $21,918,100. Imports have rarely exceeded 1 per cent of the domestic output. Exports, on the other hand, formerly ranged between 15,000,000 and 20,000,000 gal., equivalent to approximately three-fifths of the domestic production. Since the war, exports have decreased to about 10,000,000 gal. The bulk of the exports go to the United Kingdom, the Netherlands, Germany and Belgium. Prices of gum turpentine were fairly stable until 1918, when a rise started that brought the price up to $2.50 per gal. in July, 1920. After a marked decline in 1921 prices are again rising and for the first quarter of 1922 have reached about $1.25 per gal.

PRODUCTION, IMPORTS AND EXPORTS OF TURPENTINE, 1914–1921

Year	Production (Gal.)	Imports (Gal.)	Exports (Gal.)
1914	27,648,939	72,679	18,900,704
1915	23,500,000	13,680	9,464,120
1916	26,750,000	20,675	9,310,268
1917	23,650,000	18,286	8,841,875
1918	17,000,000	302	3,717,093
1919	19,271,000	1,662	10,672,102
1920	. .	43,785	9,438,423

Rosin

The other member of the naval stores family has followed practically the same trend of production as that of turpentine. In 1914, 1,408 establishments produced 4,018,000 bbl. (280 lb. each) valued at $10,572,300. In 1919, 1,214 establishments produced 2,272,100 bbl. of rosin valued at $34,695,000. The naval stores industry is located in the south Atlantic and gulf states adjacent to the pine forests. Florida is the principal producing state, contributing about 45 per cent of the total output. Georgia follows with 22 per cent. A very large proportion of the domestic output is for export. Prior to 1914 exports amounted to considerably over 2,000,000 bbl. Germany at that time was one of the principal consumers.

PRODUCTION, IMPORTS AND EXPORTS OF ROSIN, 1914–1921

Year	Production (Bbl.)	Imports (Lb.)	Exports (Bbl.)
1914	4,018,000	2,742,083	2,417,950
1915	3,452,000	1,505,790	1,372,316
1916	3,155,000	5,571,325	1,571,279
1917	3,630,000	129,848	1,638,590
1918	3,214,000	210,443	779,027
1919	2,272,000	96,044	1,209,627
1920	.....	141,635	1,164,328
1921	.....	7,115	1,001,542

PRICES OF ROSIN, WATER WHITE, 1914-1922
(Dollars per Barrel, 280 Lb.)

	1914	1915	1916	1918
Jan.	7.25–7.50	6.40	7.85	8.50
April.	6.75	6.50–6.55	6.40	8.15
July.	6.92½	6.95	7.00	12.00
Oct.	6.75	6.50	7.25	16.25
	1919	1920	1921	1922
Jan.	18.00	22.25	9.00	7.25
April.	14.50	21.75	6.00	7.25
July.	19.75	16.85	6.60	8.25
Oct.	24.00	13.25	7.40	....

Dealers in rosin seem well satisfied with the general volume of present business. Domestic consumers have shown a keener interest in the market situation and the export demand has been along moderately steady lines. Rosin B-D grades range from $6.25@$6.30 per barrel; E-I, $6.35@$6.40; K-N, $6.45@$6.65, and WG-WW, $7.80@$8.25 per barrel.

The New York Market

New York, Sept. 10, 1922.

The general tone of the chemical market during the past week was decidedly firm. Advances were recorded in several instances due to the higher cost of production resulting from the coal strike. Inquiries for home consumption were more numerous, especially for the basic commodities. A much brighter outlook has been noted in caustic soda and soda ash, with the demand for home consumption materially stronger. The previously reported firm position has been sustained in all quarters for bleaching powder. Recent buying has reduced available supplies of yellow prussiate of soda and prices reached a new high level for the year. Oxalic acid is finding a ready outlet, with prices firm. Arsenic prices remain unchanged, although demand has slackened to some extent. Bichromates have been well maintained throughout the interval and inquiries for medium-sized lots were reported in several directions. Formaldehyde prices were advanced earlier in the week, but no change in the regular routine demand has been noted.

General and Special Chemicals

Acetic Acid—First-hand sales of the 28 per cent grade are heard at $2.70 per 100 lb. The 56 per cent is moving around $5.35@$5.75 per 100 lb.

Acetate of Soda—This product has been one of the features of the market. Production is greatly limited and surplus stocks have entirely disappeared. Small quantities are reported at 7¼@7½c. per lb. Round lots are almost impossible to obtain.

Bleaching Powder—Prices are quoted firm at the recent advance. Sales were reported at $1.80@$1.90 per 100 lb. in large drums, f.o.b. works. Small drums for export have brought $2.25 per 100 lb. General offerings are very limited, with the demand quite strong.

Caustic Soda—The inquiry for home consumption has been very active during the week. Small lots of standard brands are quoted at 3¾@4c. per lb. ex-store. Producers report a steady demand for contract deliveries. Export business has been somewhat dormant.

Chlorate of Soda—Leading dealers are very firm in their views for immediate shipment material and quote 6½c. per lb. as the low figure. The demand is moderately active for consuming requirements.

Formaldehyde—Large producers announced an advance in prices to 9c. per lb. in barrels for less carload quantities. Round lots are practically non-existent on the spot market.

Oxalic Acid—This market has been exceedingly strong of late and prices were again advanced to the highest level of the year. Sales at the works were reported at 17¼@17½c. per lb. Demand has been quite active and consumers showed more interest. The spot market held at the same level as works material.
